Equal-norm tight frames have been shown to be useful for robust data transmission. The losses in the network are modeled as erasures of transmitted frame coefficients. We give the first systematic study of the general class of equal-norm tight frames and their properties. We search for efficient constructions of such frames. We show that the only equal-norm tight frames with the group structure and one or two generators are the generalized harmonic frames. Finally, we give a complete classification of frames in terms of their robustness to erasures.

1. INTRODUCTION

Frames are redundant sets of vectors in a Hilbert space which yield one natural representation for each vector in the space, but which may have infinitely many different representations for a given vector [4, 5, 6, 7, 8, 9, 10, 11, 16, 18, 20, 23]. Frames have been used in signal processing because of their resilience to additive noise [10], resilience to quantization [14], as well as their numerical stability of reconstruction [10], and greater freedom to capture signal characteristics [2, 3]. Recently, several new applications for (equal-norm tight) frames have been developed. The first, developed by Goyal, Kovačević and Vetterli [15, 25, 24, 27], uses the redundancy of a frame to mitigate the effect of losses in packet-based communication systems. Modern communication networks transport packets of data from a
source to a recipient. These packets are sequences of information bits of a certain length surrounded by error-control, addressing, and timing information that assure that the packet is delivered without errors. This is accomplished by not delivering the packet if it contains errors. Failures here are due primarily to buffer overflows at intermediate nodes in the network. So to most users, the behavior of a packet network is not characterized by random loss, but by unpredictable transport time. This is due to a protocol, invisible to the user, that retransmits lost packets. Re-transmission of packets takes much longer than the original transmission. In many applications, retransmission of lost packets is not feasible and the potential for large delay is unacceptable.

If a lost packet is independent of the other transmitted data, then the information is truly lost to the receiver. However, if there are dependencies between transmitted packets, one could have partial or complete recovery despite losses. This leads us naturally to use frames for encoding. The question, however, is: What are the best frames for this purpose? With an additive noise model for quantization, in [23], the authors show that an equal-norm frame minimizes mean-squared error if and only if it is tight. So it is this class of frames - the equal-norm Parseval tight frames - which we seek to identify and study.

Another recent important application of equal-norm Parseval tight frames is in multiple-antenna code design [17]. Much theoretical work has been done to show that communication systems which employ multiple antennas can have very high channel capacities [13, 21]. These methods rely on the assumption that the receiver knows the complex-valued Rayleigh fading coefficients. To remove this assumption, in [19] new classes of unitary space-time signals are proposed. If we have $N$ transmitting antennas and we transmit in blocks of $M$ time samples (over which the fading coefficients are approximately constant), then a constellation of $K$ unitary space-time signals is a (weighted by $\sqrt{M}$) collection of $M \times N$ complex matrices \( \{ \Phi_k \} \) for which $\Phi_k^* \Phi_k = I$. The $n$th column of any $\Phi_k$ contains the signal transmitted on antenna $n$ as a function of time. The only structure required in general is the time-orthogonality of the signals.

Originally it was believed that designing such constellations was a too cumbersome and difficult optimization problem for practice. However, in [19], it was shown that constellations arising in a “systematic” fashion can be done with relatively little effort. Systematic here means that we need to design high-rate space-time constellations with low encoding and decoding complexity. It is known that full transmitter diversity (that is, where the constellation is a set of unitary matrices whose differences have nonzero determinant) is a desirable property for good performance. In a tour-de-force, in [17], the authors used fixed-point-free groups and their representations to design high-rate constellations with full diversity. Moreover, they classified all full-diversity constellations that form a group, for all rates and numbers of transmitting antennas.

For these applications, and a host of other applications in signal processing, it has become important that we understand the class of equal-norm Parseval tight frames. In this paper, we make the first systematic study of such frames. In Section 2 we review basic notions on frames. In particular, we state the Naimark’s Theorem [1] which has been rediscovered several times in recent years [16, 12] although it has been used for several decades in operator theory. We give examples
of equal-norm Parseval tight frames such as harmonic and Gabor frames. For harmonic frames, we define a more general class - general harmonic frames (GHF) - and study when harmonic frames are equivalent to each other and general harmonic frames. In Proposition 2.5, we give a simple equivalence condition on general harmonic frames which states that the inner product between any two frame vectors \( \varphi_i \) and \( \varphi_j \) in a GHF is equal to the inner product between \( \varphi_{i+1} \) and \( \varphi_{j+1} \). Section 3 concentrates on equal-norm tight frames (ENTF). We start with a review in Section 3.1 and proceed with several ways of classifying ENTFs including providing a correspondence between subspaces of the original space and the ENTFs, obtaining ENTFs as alternate dual frames for a given frame as well as finding ENTFs through frames equivalent to them. In Section 4, we shift our attention to ENTFs with group structure. We show that the ENPTFs generated by the set \( \{ U^k \varphi_0 \}_{k=0}^{M-1} \) (where \( U \) is unitary and \( \varphi_0 \in \mathbb{H} \)) are precisely the GHFs. We then extend our discussion to ENPTFs generated by \( \{ U^k \varphi_0 \}_{k=0}^{M} \) and higher numbers of generators. Finally, Section 5 introduces erasures modeled as losses of transform coefficients \( (f, \varphi_i) \), where \( f \) is the signal to be transmitted and \( \{ \varphi_i \}_{i \in I} \) is a set of frames vectors corresponding to erased transform coefficients. We give a complete classification of frames with respect to their robustness to erasures. We study when we can obtain frames robust to a certain number of erasures as a projection from another frame with a different number of erasures.

2. FRAME REVIEW

A set of vectors \( \Phi = \{ \varphi_i \}_{i \in I} \) in a Hilbert space \( \mathbb{H} \), is called a frame if

\[
0 < A ||x||^2 \leq \sum_{i \in I} |(x, \varphi_i)|^2 < B ||x||^2 \leq +\infty, \ x \neq 0, \quad (2.1)
\]

where \( I \) is the index set and the constants \( A, B \) are called frame bounds. Although many of our results hold in more general settings, in this paper, we concentrate mostly on the \( N \)-dimensional real or complex Hilbert spaces \( \mathbb{R}^N \) and \( \mathbb{C}^N \) (which we denote \( \mathbb{H}_N \)) with the usual Euclidean inner product. When results generalize to the infinite-dimensional setting, we will point it out.

When \( A = B \) the frame is tight (TF). If \( A = B = 1 \), the frame is Parseval tight (PTF). A frame is equal-norm (ENF) if all its elements have the same norm \( c \), \( ||\varphi_i|| = c \). When \( c = 1 \), the frame is called unit-norm (UNF). For an equal-norm tight frame (ENTF), the frame bound \( A \) gives the redundancy ratio. A UNPTF, that is, an ENPTF with norm-1 vectors is an orthonormal basis (ONB).

2.1. A Digression: Notation Battle

When Vivek Goyal and Jelena Kovacević started working on frames in multiple description systems [26], they called the frames where all the frame vectors were of norm 1 - normalized frames. As they went through the more mathematically-oriented frame literature, they realized that the term “normalized” was used by many frame researchers, most notably Han and Larson [16], to denote tight frames with a frame bound equal to 1. Consequently, bowing to the frame authorities, Vivek and Jelena changed their notation from “normalized” to “uniform” and reserved the term “normalized” for tight frames with a frame bound equal to 1. This switch shows the ambiguity in notation which has arisen thanks to the two camps.
At the DIMACS Workshop on Source Coding and Harmonic Analysis, at Rutgers, NJ, in May of 2002, the self-selected “Frame Nomenclature Standardization Committee” consisting of Matt Fickus, John Benedetto, Radu Balan, Carlos Cabrelli, Pete Casazza and Jelena Kovačević, agreed to solve this problem as follows:

1. **Equal-norm frame (ENF):** Frame where all the elements have the same norm, \( \| \varphi_m \| = \| \varphi_n \| \), for all \( m \) and \( n \).

2. **Unit-norm frame (UNF):** Frame where all the elements have norm 1, \( \| \varphi_m \| = 1 \), for all \( m \).

3. **\( \lambda \)-tight frame (\( \lambda \)-TF):** Tight frame with frame bound \( \lambda \).

4. **Parseval tight frame (PTF):** Tight frame with frame bound \( \lambda = 1 \). This could also be denoted as a 1-tight frame. The motivation for this name comes from the Parseval’s equality, best known in Fourier analysis, which states that the norm of the signal we are considering is equal to the norm of the signal in the “transformed domain”.

This diplomatic solution was agreeable to everyone and thus we decided to adopt it. Whether it will be followed, remains to be seen.

### 2.2. Back to Frames

The **analysis frame operator**\(^1\) \( F \) maps the Hilbert space \( \mathbb{H} \) into \( \ell_2(I) \)

\[
(Fx)_i = \langle \varphi_i, x \rangle,
\]

for \( i \in I \). When \( \mathbb{H} = \mathbb{H}_N \), the analysis frame operator is an \( M \times N \) matrix whose rows are the transposed frame vectors \( \varphi_i^* \):

\[
F = \begin{pmatrix}
\varphi_{i1}^* & \cdots & \varphi_{iN}^* \\
\vdots & \ddots & \vdots \\
\varphi_{M1}^* & \cdots & \varphi_{MN}^*
\end{pmatrix}.
\]

We say that two frames \( \{ \varphi_i \}_{i \in I} \) and \( \{ \psi_i \}_{i \in I} \) for \( \mathbb{H} \) are **equivalent** if there is an invertible operator \( L \) on \( \mathbb{H} \) for which \( L\varphi_i = \psi_i \) for all \( i \in I \), and they are **unitarily equivalent** if \( L \) can be chosen to be a unitary operator. If \( \{ \varphi_i \}_{i \in I} \) is a frame with frame bounds \( A, B \), and if \( P \) is an orthogonal projection on \( \mathbb{H} \), then by (2.1) we have that \( \{ P \varphi_i \}_{i \in I} \) is a frame for \( P\mathbb{H} \) with frame bounds \( A \) and \( B \). In particular, if \( \{ \varphi_i \}_{i \in I} \) is a Parseval tight frame for \( \mathbb{H} \) (for example, if it is an orthonormal basis for \( \mathbb{H} \)), then \( \{ P \varphi_i \}_{i \in I} \) is a Parseval tight frame for \( P\mathbb{H} \).

The following theorem tells us that every Parseval tight frame can be realized as a projection of an orthonormal basis from a larger space. It serves as a converse to the observation above that orthogonal projections of Parseval tight frames produce Parseval tight frames for their span.

**Theorem 2.1** (Naimark [1], Han & Larson [16]). \(^2\) A set \( \{ \varphi_i \}_{i \in I} \) in a Hilbert space \( \mathbb{H} \) is a Parseval tight frame for \( \mathbb{H} \) if and only if there is a larger Hilbert space

\(^1\)F is sometimes called just frame operator. Here, we use analysis frame operator for \( F \), synthesis frame operator for \( F^* \) and frame operator for \( F^*F \).

\(^2\)This theorem has been rediscovered by several people in recent years. The second author first heard it from I. Daubechies in the mid-90’s. Han and Larson rediscovered it in [16]; they came up...
Let us now go through certain important frame notions. Using the analysis frame operator $F$, (2.1) can be rewritten as

$$A I \leq F^* F \leq B I.$$  \hfill (4)

We call $S = F^* F$ the frame operator. It follows that $S$ is invertible (Lemma 3.2 in [10]), and furthermore

$$B^{-1} I \leq S^{-1} \leq A^{-1} I.$$  \hfill (5)

It follows that $\{\varphi_i\}_{i \in I}$ is a Parseval tight frame if and only if $F$ is an isometry.

Also, $S$ is a positive self-adjoint invertible operator on $\mathbb{H}$ and $S = A I$ if and only if the frame is tight. In finite dimensions, the canonical dual frame of $\Phi$ is a frame defined as $\hat{\Phi} = \{\hat{\varphi}_i\}_{i=1}^M = \{S^{-1} \varphi_i\}_{i=1}^M$, where

$$\hat{\varphi}_i = S^{-1} \varphi_i,$$  \hfill (6)

for $k = 1, \ldots, M$. Now,

$$f = \sum_{i \in I} (f, S^{-1} \varphi_i) \varphi_i,$$

for all $f \in H$.

So the canonical dual frame can be used to reconstruct the elements of $\mathbb{H}$ from the frame. However, there may be other sequences in $\mathbb{H}$ which give reconstruction. This formula points out both the strengths and weaknesses of frames. First, we see that every element $f \in H$ has at least one natural series representation in terms of the frame elements. Also, this element may have infinitely many other representations. However, in order to find this natural representation of $f$, we need to invert the frame operator, which may be difficult or even impossible in practice. The best frames then are clearly the tight frames since in this case the frame operator becomes a multiple of the identity.

Noting that $\hat{\varphi}_i^* = \varphi_i^* S^{-1}$ and stacking $\hat{\varphi}_1^*, \hat{\varphi}_2^*, \ldots, \hat{\varphi}_M^*$ in a matrix, the frame operator associated with $\hat{\Phi}$ is

$$\hat{F} = FS^{-1}.$$  \hfill (7)

Since $\hat{F}^* \hat{F} = S^{-1}$, (5) shows that $B^{-1}$ and $A^{-1}$ are frame bounds for $\hat{\Phi}$.

Another important concept is that of a pseudo-inverse $F^\dagger$. It is the analysis frame operator associated with the dual frame,

$$F^\dagger = \hat{F}^*.$$  \hfill (8)

with the idea that a frame could be obtained by compressing a basis in a larger space and that the process is reversible (the statement in this paper is due to Han and Larson). Finally, it was pointed out to the second author by E. Soljanin [22] that this is, in fact, the Naimark’s theorem, which has been widely known in operator theory and has been used in quantum theory.
Note that for any matrix $F$ with rows $\varphi_i$:

$$S = F^*F = \sum_{i=1}^{M} \varphi_i \varphi_i^*.$$  \hfill (9)

This identity will prove to be useful in many proofs.

Another interesting fact is that $\{S^{-1/2} \varphi_i\}$ is a Parseval tight frame for any frame $\{\varphi_i\}$. Thus, every frame is equivalent to a Parseval tight frame.

### 2.3. The Role of Eigenvalues

The product $S = F^*F$ will appear everywhere and its eigenstructure will play an important role. Denote by $\lambda_k$’s the eigenvalues of $S = F^*F$. We now summarize the important eigenvalue properties.

**General Frame.** For any frame in $\mathbb{H}_N$, the sum of the eigenvalues of $S = F^*F$, equals the sum of the lengths of the frame vectors:

$$\sum_{k=1}^{N} \lambda_k = \sum_{i=1}^{M} ||\varphi_i||^2.$$  \hfill (10)

**Equal-Norm Frame.** For an equal-norm frame, that is, when $||\varphi_i|| = c$, $i = 1, \cdots, M$,

$$\sum_{k=1}^{N} \lambda_k = \sum_{i=1}^{M} ||\varphi_i||^2 = M \cdot c^2.$$  \hfill (11)

**Tight Frame.** Since tightness means $A = B$, for a TF, we have from (2.1)

$$\sum_{i=1}^{M} |(f, \varphi_i)|^2 = A||f||^2,$$  \hfill (12)

for all $f \in \mathbb{H}_N$. Moreover, according to (5), a frame is a TF if and only if

$$F^*F = A \cdot I_N.$$  \hfill (13)

Thus, for a TF, all the eigenvalues of the frame operator $S = F^*F$ are equal to $A$. Then, using (10), the sum of the eigenvalues of $S = F^*F$ is as follows:

$$N \cdot A = \sum_{k=1}^{N} \lambda_k = \sum_{i=1}^{M} ||\varphi_i||^2.$$  \hfill (14)

**Parseval Tight Frame.** If a frame is a PTF, that is, $A = B = 1$, then

$$\sum_{i=1}^{M} |(f, \varphi_i)|^2 = ||f||^2.$$  \hfill (15)
for all $f \in \mathbb{H}_N$. In operator notation, a frame is a PTF if and only if
\[ S = F^*F = I_N. \]  
(16)

For a PTF, all the eigenvalues of $S = F^*F$ are equal to 1. Then, using (10), the sum of the eigenvalues of $S = F^*F$ is as follows:
\[ N = \sum_{k=1}^{N} \lambda_k = \sum_{i=1}^{M} ||\varphi_i||^2. \]  
(17)

**Equal-Norm Tight Frame.** From (11) and (14), we see that
\[ N \cdot A = \sum_{k=1}^{N} \lambda_k = \sum_{i=1}^{M} ||\varphi_i||^2 = M \cdot c^2. \]  
(18)

Then, from (12) and (18),
\[ \sum_{i=1}^{M} |\langle f, \varphi_i \rangle|^2 = \frac{M}{N} c^2 ||f||^2, \]  
(19)

for all $f \in \mathbb{H}_N$. The **redundancy ratio** is then
\[ A = \frac{M}{N} \cdot c^2. \]  
(20)

Since $S = F^*F = (M/N)I$, the following is obvious:
\[ \sum_{i=1}^{M} |\varphi_i|^2 = \frac{M}{N}. \]  
(21)

**Equal-Norm Parseval Tight Frame.** If a frame is an ENPTF, that is, we also ask for $A = B = 1$, and if the frame vectors have norm $c$, then
\[ N = \sum_{k=1}^{N} \lambda_k = \sum_{i=1}^{M} ||\varphi_i||^2 = c^2 M. \]

Thus, an UNPTF, that is, when $c = 1$, is an orthonormal basis.

The following proposition describes unitary equivalence for ENPTFs.

**Proposition 2.1.** If $\{\varphi_k\}$ is a frame for $\mathbb{H}$ with the frame operator $S$, and $T$ is an invertible operator on $\mathbb{H}$, then $TST^*$ is the frame operator for the frame $\{T\varphi_k\}$. In particular, if $\{\varphi_k\}$ is an ENPTF then every frame unitarily equivalent to $\{\varphi_k\}$ is also a ENPTF.

**Proof.** (Proposition 2.1). Let $L$ be the frame operator for $\{T\varphi_k\}$. For any $f \in H$ we have:
\[ Lf = \sum_k \langle f, T\varphi_k \rangle T\varphi_k = T \left( \sum_k \langle T^* f, \varphi_k \rangle \varphi_k \right) = T[S(T^*)f]. \]
2.4. Examples of Equal-Norm Parseval Tight Frames

We start with a simple example of a frame; three vectors in two dimensions. The particular frame we examine is termed *Mercedes-Benz (MB)* frame (for obvious reasons, just draw the vectors). The ENPTF version of it is given by the analysis frame operator

\[
F = \sqrt{\frac{2}{3}} \begin{pmatrix}
0 & 1 \\
-\sqrt{3}/2 & -1/2 \\
\sqrt{3}/2 & -1/2
\end{pmatrix}.
\]  
(22)

This is obviously an ENPTF since \((2/3)F^*F = I\). We could make this frame just an ENTF with norm 1 (as in [25]) by having the analysis frame operator be simply \(F\).

We now review two general classes of equal-norm tight frames which are commonly used. The (general) harmonic frames and the tight Gabor frames. More general classes of equal-norm tight frames are the full-diversity constellations that form a group given in [17].

2.5. Harmonic Frames

*Harmonic tight frames* (HTF) are obtained by keeping the first \(N\) coordinates of an \(M \times M\) discrete Fourier transform basis as in Naimark’s Theorem 2.1. They have been proven to be useful in applications [19].

An HTF is given by:

\[
\varphi_k = \frac{1}{\sqrt{M}}(w_1^k, w_2^k, \ldots, w_N^k),
\]  
(23)

for \(k = 0, \ldots, M - 1\), where \(w_i\) are distinct \(M\)th roots of unity.\(^3\) This is thus a PTF, that is, \(F^*F = I\). A more general definition of the harmonic frame (general harmonic frame) is as follows:

**Definition 2.1.** Fix \(M \geq N\), \(|c| = 1\) and \(\{b_i\}_{i=1}^N\) with \(|b_i| = \frac{1}{\sqrt{M}}\). Let \(\{c_i\}_{i=1}^N\) be distinct \(M\)th roots of \(c\), and for \(0 \leq k \leq M - 1\), let

\[
\varphi_k = (c_1^k b_1, c_2^k b_2, \ldots, c_N^k b_N).
\]

Then \(\{\varphi_k\}_{k=0}^{M-1}\) is an equal-norm Parseval tight frame for \(\mathbb{H}_N\). Any frame unitarily equivalent to one of these is called a *general harmonic frame* (GHF).

We will now examine the general harmonic frames in detail. Our goal is to determine their relationship to HTFs. We start by showing that the harmonic frames (not GHF) are unique up to a permutation of the orthonormal basis (that is, if and only if their columns are permutations of each other).

**Proposition 2.2.** Let \(\{\varphi_k\}_{k=0}^{M-1}\) and \(\{\psi_k\}_{k=0}^{M-1}\) be harmonic frames on \(\mathbb{H}_N\). Then \(\{\varphi_k\}_{k=0}^{M-1}\) is equivalent to \(\{\psi_k\}_{k=0}^{M-1}\) if and only if there is a permutation \(\sigma\) of \(\mathbb{Z}/M\mathbb{Z}\) such that \(\psi_k = \varphi_{\sigma(k)}\).

\(^3\)Note that in the engineering literature, the normalization is \(1/\sqrt{N}\).
\{1, 2, \cdots, N\} so that \(\varphi_{kj} = \psi_{k\sigma(j)}\), for all \(0 \leq k \leq M-1\) and all \(1 \leq j \leq N\). Hence, two harmonic frames are equivalent if and only if they are unitarily equivalent.

**Proof** (Proposition 2.2). Let \(\{e_j\}_{j=1}^N\) be the natural orthonormal basis for \(\mathbb{H}_N\) and

\[
\varphi_k = (w_1^k, w_2^k, \ldots, w_N^k) = \sum_{j=1}^N w_j^k e_j,
\]

and

\[
\psi_k = (v_1^k, v_2^k, \ldots, v_N^k) = \sum_{j=1}^N v_j^k e_j,
\]

where \(w_j, v_j\) are sets of distinct \(M\)th roots of unity. If

\[
\{w_j|1 \leq j \leq N\} \neq \{v_j|1 \leq j \leq N\},
\]

then, without loss of generality, we may assume that \(v_1 \notin \{w_j|1 \leq j \leq N\}\). Therefore,

\[
\sum_{k=0}^{M-1} \overline{\tau}_1^k \varphi_k = \sum_{j=1}^N \left(\sum_{k=0}^{M-1} \overline{\tau}_1^k w_j \right) e_j = \sum_{j=1}^N 0 \cdot e_j = 0.
\]

On the other hand,

\[
\sum_{k=0}^{M-1} \overline{\tau}_1^k \psi_k(1) = \sum_{k=0}^{M-1} |v_1^k|^2 = M.
\]

It follows that \(\{\varphi_k\}_{k=0}^{M-1}\) is not equivalent to \(\{\psi_k\}_{k=0}^{M-1}\). The other direction is immediate. \(\blacksquare\)

We now show that every general harmonic frame is unitarily equivalent to a simple variation of a harmonic frame.

**Proposition 2.3.** Every general harmonic frame is unitarily equivalent to a frame of the form \(\{c^k \psi_k\}_{k=0}^{M-1}\), where \(|c| = 1\) and \(\{\psi_k\}_{k=0}^{M-1}\) is a harmonic frame.

**Proof** (Proposition 2.3). Let \(M \geq N\), \(|c| = 1\) and \(|b_k| = 1/\sqrt{M}\), for all \(1 \leq k \leq N\). Let \(\{e_j\}_{j=1}^N\) be distinct \(M\)th roots of \(c\) and consider the GHF,

\[
\varphi_k = (c_1^k b_1, c_2^k b_2, \ldots, c_N^k b_N),
\]

for all \(0 \leq k \leq M - 1\). If \(c = e^{i\theta}\), let \(d = e^{i\theta/M}\). Then there exist distinct \(M\)th roots of unity \(w_1, w_2, \ldots, w_N\) with \(c_j = e^{i\theta/M} w_j = dw_j\). For all sets of complex numbers \(\{a_k\}_{k=0}^{M-1}\) we have:

\[
\sum_{k=0}^{M-1} a_k \varphi_k = \sum_{j=1}^N \left| \sum_{k=0}^{M-1} a_k c_j^k b_j \right|^2 = \frac{1}{M} \sum_{j=1}^N \sum_{k=0}^{M-1} |a_k c_j^k|^2 =
\]
\[ \frac{1}{M} \sum_{j=1}^{N} \sum_{k=0}^{M-1} |a_k e^{i k\theta/ M} w_j^k|^2 = \frac{1}{M} \| \sum_{k=0}^{M-1} a_k \psi_k \|^2, \]

where \( \psi_k = (w_1^k, w_2^k, \ldots, w_N^k) \). Thus, the GHF \( \{ \varphi_k \}_{k=0}^{M-1} \) is unitarily equivalent to \( \frac{1}{\sqrt{M}} \{ \psi_k \}_{k=0}^{M-1} \), with \( \{ \psi_k \}_{k=0}^{M-1} \) an HTF. □

Finally, we show that the frames given in Proposition 2.3 are not unitarily equivalent to each other or to harmonic frames except in the trivial case.

**Proposition 2.4.** Let \( \{ \varphi_k \}_{k=0}^{M-1} \) and \( \{ \psi_k \}_{k=0}^{M-1} \) be harmonic frames and let \(|c| = 1\). Then \( \{ c^k \varphi_k \}_{k=0}^{M-1} \) is equivalent to \( \{ c^k \psi_k \}_{k=0}^{M-1} \) if and only if \( c \) is an \( M \)th root of unity and there is a permutation \( \sigma \) of \( \{ 1, 2, \ldots, N \} \) so that \( \varphi_{k_j} = \psi_{\sigma(k_j)} \), for all \( 0 \leq k \leq M - 1 \) and \( 1 \leq j \leq N \). In particular, a general harmonic frame is unitarily equivalent to a harmonic tight frame if and only if it equals a harmonic tight frame.

**Proof (Proposition 2.4).** Let \( \varphi_k = \sum_{j=1}^{N} w_j^k e_j \), for all \( 0 \leq k \leq M-1 \). If \( c = w_j^{-1} \), for some \( j \), we are done. Otherwise, since \( \sum_{k=0}^{M-1} \psi_k = 0 \), if \( \{ c^k \varphi_k \} \) is equivalent to \( \{ \psi_k \} \) then also \( \sum_{k=0}^{M-1} c^k \varphi_k = 0 \). Hence, for all \( 1 \leq j \leq N \) we have

\[ \sum_{k=0}^{M-1} c^k w_j^k = \sum_{k=0}^{M-1} (cw_j)^k = \frac{1 - (cw_j)^M}{1 - cw_j} = 0. \]

Hence, \( (cw_j)^M = c^M w_j^M = c^M = 1 \). The proposition now follows from Proposition 2.2. □

We now have immediately,

**Corollary 2.1.** Let \( \{ \varphi_k \}_{k=0}^{M-1} \) and \( \{ \psi_k \}_{k=0}^{M-1} \) be harmonic frames and let \(|c| = |d| = 1\). The frames \( \{ c^i \varphi_k \}_{k=0}^{M-1} \) and \( \{ d^j \psi_k \}_{k=0}^{M-1} \) are equivalent if and only if \( c = d \) and there is a permutation \( \sigma \) of \( \{ 1, 2, \ldots, N \} \) so that \( \varphi_{k_j} = \psi_{\sigma(k_j)} \), for all \( 0 \leq k \leq M - 1 \).

The next proposition gives a classification of GHFs.

**Proposition 2.5.** A set \( \{ \varphi_i \}_{i=0}^{M-1} \) in \( \mathbb{H}_N \) is a GHF if and only if for all \( 0 \leq i, j \leq M - 1 \) we have

\[ \langle \varphi_i, \varphi_j \rangle = \langle \varphi_{i+1}, \varphi_{j+1} \rangle, \]

where \( \varphi_M = \varphi_0 \).

**Proof.** Note that \( \{ \varphi_i \}_{i=0}^{M-1} \) satisfies the equality in the proposition if and only if \( \{ V \varphi_i \}_{i=0}^{M-1} \) satisfies it for every unitary operator \( V \) on \( \mathbb{H}_N \). So, by Proposition 4.1, we may assume our GHF is of the form \( \{ U^i \varphi_0 \}_{i=0}^{M-1} \) where \( U \) is a unitary operator on \( \mathbb{H}_N \). Hence, for all \( 0 \leq i, j \leq M - 1 \) we have

\[ \langle \varphi_{i+1}, \varphi_{j+1} \rangle = \langle U^{i+1} \varphi_0, U^{j+1} \varphi_0 \rangle = \langle U^i \varphi_0, U^j \varphi_0 \rangle = \langle \varphi_i, \varphi_j \rangle. \]
Conversely, given our equality, for any sequence of scalars \( \{a_i\}_{i=0}^{M-1} \),
\[
\| \sum_{i=0}^{M-1} a_i \varphi_{i+1} \|^2 = \left( \sum_{i=0}^{M-1} a_i \varphi_{i+1}, \sum_{i=0}^{M-1} a_i \varphi_{i+1} \right) \\
= \sum_{i,j=0}^{M-1} a_i \overline{a}_j \langle \varphi_{i+1}, \varphi_{j+1} \rangle = \sum_{i,j=0}^{M-1} a_i \overline{a}_j \langle \varphi_i, \varphi_j \rangle \\
= \langle \sum_{i=0}^{M-1} a_i \varphi_i, \sum_{i=0}^{M-1} a_i \varphi_i \rangle = \| \sum_{i=0}^{M-1} a_i \varphi_i \|^2.
\]

It follows that \( U \varphi_i = \varphi_{i+1} \) is a unitary operator and \( U^i \varphi_0 = \varphi_i \), for all \( 0 \leq i \leq M-1 \). ■

As we will see in the next section, ENTFs with \( M = N + 1 \) are all unitarily equivalent. Thus, as a direct consequence of Theorem 3.3, any ENTF with \( M = N + 1 \) is unitarily equivalent to the HTF with \( M = N + 1 \). This is a very useful result since we have HTFs for any \( N \) and \( M \); thus, for \( M = N + 1 \), we always have an expression for all ENTFs. For example, this means that the MB frame we introduced earlier is equivalent to the HTF with \( M = 3 \) and \( N = 2 \).

Another interesting property of an HTF is that it is the only ENPTF such that its elements are generated by a group of unitary operators with one generator, as we will see in Section 4. That is, \( \Phi = \{ \varphi_i \}_{i=1}^{M} = \{ U^i \varphi_0 \}_{i=1}^{M} \), where \( U \) is a unitary operator.

Moreover, HTFs have a very convenient property when it comes to erasures. We can erase any \( e \leq (M - N) \) elements from the original frame and what is left is still a frame (Theorem 4.2 from [25]). We provide a complete classification of frames in terms of their robustness to erasures in Section 5.

### 2.6. Gabor or Weyl-Heisenberg Frames

For the other general class of frames, we introduce two special operators on \( L_2(\mathbb{R}) \). Fix \( 0 < a, b \) and for \( f \in L_2(\mathbb{R}) \) define translation by \( a \) as

\[
T_a f(t) = f(t - a),
\]

and modulation by \( b \) as

\[
E_b f(t) = e^{2\pi ibt} f(t).
\]

Now, fix \( g \in L_2(\mathbb{R}) \). If \( \{ E_m T_n g \}_{m,n \in \mathbb{Z}} \) is a frame for \( L_2(\mathbb{R}) \), we call it a Gabor frame (or a Weyl-Heisenberg frame). It is clear that in this class the frames are equal-norm. Also, since the frame operator \( S \) for a Gabor frame \( \{ E_m T_n g \}_{m,n \in \mathbb{Z}} \) must commute with translation and modulation, each Gabor frame is equivalent to the (equal-norm) Parseval tight Gabor frame \( \{ E_m T_n S^{-1/2} g \}_{m,n \in \mathbb{Z}} \). For an introduction to Gabor frames we refer the reader to [7] and [18].
3. **EQUAL-NORM TIGHT FRAMES**

3.1. **What is Known about ENTFs?**

As we have mentioned in the introduction, ENTFs have become popular in applications. In particular, in [25], the authors attack the problem of robust transmission over the Internet by using frames. Being redundant sets of vectors, they provide robustness to losses, which are modeled as erasures of certain frame coefficients. It is further shown in [25] that, assuming a particular quantization model, an equal-norm frame with quantized coefficients, minimizes mean-squared error if and only if it is tight. Moreover, the same is true when we consider one erasure and look at both the average- and worst-case MSE.

As a result, our aim is to construct useful sets of frames for such applications. To that end, it is important to classify equal-norm Parseval tight frames in order to facilitate the search for useful sets.

Our notion of usefulness includes any sets which would be computationally efficient; for example, those that can be obtained from one or more generating vectors or those with a simple structure, for example, such that any of the frame operators could be expressed as a product of sparse matrices.

Finally, we are interested in the robustness of our frames to coefficient (frame vector) erasures. These and other issues will be explored in the rest of the paper.

3.1.1. **Construction of ENTFs**

There is a general well known method for getting finite ENTFs. We state this result here in its standard form and will give a new proof of the result in Section 5. In Section 5 we will also extend this result to equal-norm frames.

**Theorem 3.1.** There is a unique way to get ENTFs with $M$ elements in $\mathbb{H}_N$. Take any orthonormal set $\{w_k\}_{k=1}^N$ in $\mathbb{H}_M$ which has the property

$$\sum_{k=1}^N |w_{kd}|^2 = \frac{N}{M}, \text{ for all } i.$$ 

Thinking of the $w_k$ as row vectors, switch to the $M$ column vectors and divide by $\sqrt{N/M}$. That is, our ENTF $\{\varphi_i\}_{i=1}^M$ is

$$\varphi_i = \sqrt{\frac{M}{N}} \sum_{k=1}^N w_{kd} e_k,$$

where $\{e_k\}_{k=1}^N$ is an orthonormal basis for $\mathbb{H}_N$. Then $||\varphi_i||^2 = 1$. This set is a equal-norm tight frame for $\mathbb{H}_M$ with $M$ elements, and all ENTFs for $\mathbb{H}_N$ with $M$ elements are obtained in this way.

There is a detailed discussion concerning the unit-norm tight frames for $\mathbb{R}^2$ in [25]. In [17], there is a deep classification of groups of unitary operators which generate unit-norm tight frames. The simplest case of this is the harmonic frames. In Section 4 we do not assume that we have a “group” of unitaries, but instead conclude that our set of unitaries must be a group.

The picture becomes much more complicated if the unit-norm tight frame is generated by a group of unitaries with more than one generator (see [17]) or worse, if the equal-norm tight frame comes from a subset of the elements of such a group.
3.1.2. Classification of ENTFs

Although we would like to classify all equal-norm tight frames, especially those which can be obtained by reasonable algorithms, this is an impossible task in general. The following theorem shows that every finite set of norm-1 vectors in a Hilbert space can be extended to become an equal-norm tight frame.

**Theorem 3.2.** If \( \{ \varphi_i \}_{i=1}^M \) is a set of norm-1 vectors in a Hilbert space \( \mathbb{H} \), then there is a unit-norm tight frame for \( \mathbb{H} \) which contains the set \( \{ \varphi_i \}_{i=1}^M \).

**Proof.** (Theorem 3.2). For each \( 1 \leq i \leq M \) choose an orthonormal basis \( \{ e_{ij} \}_{j \in J} \) for \( H \) which contains the vector \( \varphi_i \). Now the set \( \{ e_{ij} \}_{i=1,j \in J} \) is made up of norm-1 vectors and for any \( f \in \mathbb{H} \) we have

\[
\sum_{i=1}^M \sum_{j \in J} |\langle f, e_{ij} \rangle|^2 = \sum_{i=1}^M \|f\|^2 = M \|f\|^2.
\]

In the above construction we get as a tight frame bound the number of elements \( M \) in the set \( \{ \varphi_i \}_{i=1}^M \). In general, this is the best possible. For example, just let \( \varphi_i = \varphi_j \) be norm-1 vectors for all \( 1 \leq i, j \leq M \). Then

\[
\sum_{j=1}^M |\langle \varphi_i, \varphi_j \rangle|^2 = M.
\]

Hence, any tight frame containing the set \( \{ \varphi_i \} \) has the tight frame bound at least \( M \).

There is another general class of equal-norm tight frames (see [25]). The result below tells us that all ENPTFs with \( M = N + 1 \) are unitarily equivalent. It is a direct consequence of Theorem 2.6 from [25] where it is stated for UNTFs.

**Theorem 3.3.** (Goyal, Kovačević and Kelner [25]). A set \( \{ \varphi_i \}_{i=1}^{N+1} \) is an equal-norm Parseval tight frame for \( \mathbb{H}_N \) if and only if \( \{ \varphi_i \}_{i=1}^{N+1} \) is unitarily equivalent to the frame \( \{ Pe_i \}_{i=1}^{N+1} \) where \( \{ e_i \}_{i=1}^{N+1} \) is an orthonormal basis for \( \mathbb{H}_{N+1} \) and \( P \) is the orthogonal projection of \( \mathbb{H}_{N+1} \) onto the orthogonal complement of the one-dimensional subspace of \( \mathbb{H}_{N+1} \) spanned by \( \sum_{i=1}^{N+1} e_i \).

Since there are HTFs with \( N + 1 \) elements in \( \mathbb{H}_N \), it follows that every ENPTF for \( \mathbb{H}_N \) with \( N + 1 \) elements is unitarily equivalent to an HTF.

3.2. Parseval and Equal-Norm Tight Frames and Subspaces of the Hilbert Space

Here, we begin to classify PTFs and ENPTFs by providing a correspondence with subspaces of the original Hilbert space. We give two results, one for PTFs and another for ENPTFs. Note that these results hold for equivalence classes of PTFs and ENPTFs. The material in this section grew out of conversations between the first author and V. Paulsen.

As we saw in Theorem 2.1, there is a unique way to get Parseval tight frames in \( \mathbb{H}_N \) with \( M \) elements. Namely, we take an orthonormal basis \( \{ e_i \}_{i=1}^M \) for \( \mathbb{H}_M \).
and take the orthogonal projection $P_{\mathbb{H}^N}$ of $\mathbb{H}^N$ onto $\mathbb{H}^N$. Then $\{P_{\mathbb{H}^N}e_i\}_{i=1}^M$ is a Parseval tight frame for $\mathbb{H}^N$ with $M$ elements. In particular, there is a natural correspondence between the Parseval tight frames for $\mathbb{H}^N$ with $M$ elements and the orthonormal bases for $\mathbb{H}^M$. Then, the equal-norm Parseval tight frames for $\mathbb{H}^N$ are the ones for which $\|P_{\mathbb{H}^N}e_i\| = \|P_{\mathbb{H}^N}e_j\|$, for all $1 \leq i, j \leq M$. We use this to exhibit a natural correspondence between these sets and certain subspaces of $\mathbb{H}^M$. Here we treat two frames as the same if they are unitarily equivalent.

**Theorem 3.4.** Let $P$ be a rank-$N$ orthogonal projection on $\mathbb{H}^M$ and let $\{e_i\}_{i=1}^M$ be an orthonormal basis for $\mathbb{H}^M$. There is a natural one-to-one correspondence between the equivalence classes of Parseval tight frames for $P\mathbb{H}^M$ with $M$ elements and the set of all $N$-dimensional subspaces of $\mathbb{H}^M$.

**Proof.** (Theorem 3.4). If $\{\varphi_i\}_{i=1}^M$ is any Parseval tight frame for $P\mathbb{H}^M$, then by Naimark's Theorem, there is an orthonormal basis $\{e'_i\}_{i=1}^M$ for $\mathbb{H}^M$ so that $Pe'_i = \varphi_i$. Define a unitary operator $U$ on $\mathbb{H}^M$ by $Ue_i = e_i$. Now, $\varphi_i = PUe_i$ which is unitarily equivalent to $\varphi_i' = U^*PUe_i$. So we will associate our Parseval tight frame $\{\varphi_i\}$ with the subspace $U^*P\mathbb{H}^M$. Now we need to check that this correspondence is one-to-one. Let $\{\psi_i\}$ be another Parseval tight frame for $P\mathbb{H}^M$ which is associated with the same subspace of $\mathbb{H}^M$, namely $U^*P\mathbb{H}^M$. Then there is an orthonormal basis $\{e''_i\}$ and a unitary operator $Ve_i = e''_i$ with $V^*PV = U^*PU$ and $PVe_i = e''_i$. Hence, $V^*PVe_i = V^*\psi_i = U^*PUe_i = U^*\varphi_i$. This implies that the Parseval tight frames $\{\varphi_i\}$ and $\{\psi_i\}$ are unitarily equivalent (and hence the same). Finally, we need to see that this correspondence covers all subspaces. If $W$ is any subspace of $\mathbb{H}^M$ of dimension $N$, we can define a unitary operator $U$ on $\mathbb{H}^M$ so that $UW = P\mathbb{H}^M$. Then $U^*PW = P_W$ while $\{PUe_i\}_{i=1}^M$ is a Parseval tight frame for $P\mathbb{H}^M$ (which under our association corresponds to $W$). ■

One of the consequences of the above result is that if we have one Parseval tight frame for $\mathbb{H}^N$, then all the others can be obtained from it by this process. We now turn our attention to equal-norm frames:

**Theorem 3.5.** Fix an orthonormal basis $\{e_i\}_{i=1}^M$ for $\mathbb{H}^M$ so that if $P$ is the orthogonal projection of $\mathbb{H}^M$ onto $\mathbb{H}^N$ then $\{Pe_i\}_{i=1}^M$ is an equal-norm Parseval tight frame for $\mathbb{H}^N$. Then there is a natural one-to-one correspondence between the equivalence classes of equal-norm Parseval tight frames for $\mathbb{H}^N$ with $M$ elements and the subspaces $W$ of $\mathbb{H}^M$ for which $\|P_We_i\|^2 = M/N$, for all $1 \leq i \leq M$.

**Proof.** (Theorem 3.5). We already have our classification of the Parseval tight frames in terms of all subspaces. Now we need to see which of these subspaces correspond to the equal-norm Parseval tight frames. Suppose $U$ is any unitary operator on $H$ so that $\{PUe_i\}$ is an equal-norm Parseval tight frame for $P\mathbb{H}^M$. Then this frame is associated to the subspace $W = U^*P\mathbb{H}^M$ and $P_W = U^*PU$. Hence, $PUe_i = UPWe_i$ for all $i$. But, $\{PUe_i\}$ is an equal-norm Parseval tight frame for $P\mathbb{H}^M$ and so $\|PUe_i\|^2 = N/M$, for all $i$. Hence,

$$\|PUe_i\|^2 = \frac{N}{M} = \|UPWe_i\| = \|P_We_i\|.$$
So our association between Parseval tight frames and subspaces given in Theorem 3.4 identifies the subspaces $W$ of $\mathbb{H}_M$ for which $\|P_W e_i\| = N/M,$ for all $i.$ 

### 3.3. Equal-Norm Dual Frames

Another method for classifying ENTFs uses a back door: get ENTFs as alternate dual frames for a given frame. To do this, we need the definition of alternate dual frames:

**Definition 3.1.** Let $\{\varphi_i\}_{i \in I}$ be a frame for a Hilbert space $\mathbb{H}.$ A set $\{\psi_i\}_{i \in I}$ is called an *alternate dual frame* for $\{\varphi_i\}_{i \in I}$ if

$$f = \sum_{i \in I} \langle f, \psi_i \rangle \varphi_i, \quad \text{for all } f \in \mathbb{H}.$$ 

In Definition 3.1, if we let $F_1$ (respectively, $F_2$) be the analysis frame operators for $\{\varphi_i\}$ (respectively $\{\psi_i\}$), then we see that $F_2^*F_1 = I.$

There are many alternate dual frames for a given frame. In fact, a frame has a unique alternate dual frame (the canonical dual frame) if and only if it is a Riesz basis [16]. Moreover, no two distinct alternate dual frames for a given frame are equivalent [16]. For a Parseval tight frame, its canonical dual frame is the frame itself since $F = FS^{-1} = F \cdot I = F.$ Moreover,

**Proposition 3.1.** If $\{\varphi_i\}_{i \in I}$ is a Parseval tight frame for $\mathbb{H}_N,$ then the only Parseval tight alternate dual frame for $\{\varphi_i\}_{i \in I}$ is $\{\varphi_i\}_{i \in I}$ itself.

**Proof.** (Proposition 3.1.) Let $F_1$ be the analysis frame operator for $\{\varphi_i\}_{i \in I}.$ Let $\{\psi_i\}_{i \in I}$ be any Parseval tight alternate dual frame for $\{\varphi_i\}_{i \in I}$ with analysis frame operator $F_2.$ It follows that $F_1, F_2$ are isometries. Now,

$$F_2^*(F_1 - F_2) = F_2^* F_1 - F_2^* F_2 = I - I = 0.$$ 

Hence, for every $f, g \in \mathbb{H}$ we have

$$\langle F_2 g, (F_1 - F_2)f \rangle = \langle g, F_2^*(F_1 - F_2)f \rangle = \langle g, 0 \rangle = 0.$$ 

Since $\{\varphi_i\}_{i \in I}$ is a PTF, for every $f \in \mathbb{H}$ we have

$$\|f\|^2 = \sum_{i=1}^M |\langle f, \varphi_i \rangle|^2 = \|F_1 f\|^2. \quad (24)$$

We can further expand this as

$$\|F_1 f\|^2 = \|(F_1 \pm F_2) f\|^2 = \|F_2 f\|^2 + \|(F_1 - F_2)f\|^2 + \underbrace{\langle F_2^*(F_1 - F_2)f, f \rangle}_{0} + \underbrace{\langle F_2^*(F_1 - F_2)f, f \rangle}_{0}.$$ 

However, since $F_2$ corresponds to a PTF as well,

$$\|F_2 f\|^2 + \|(F_1 - F_2)f\|^2 = \|f\|^2 + \|(F_1 - F_2)f\|^2. \quad (25)$$
Equating (24) and (25), we get
\[ \| (F_1 - F_2) f \|^2 = 0. \]
Hence, \( F_1 = F_2 \) and so \( \varphi_i = \psi_i \), for all \( i \in I \). □

If we ask for the dual frame just to be tight, but not Parseval, then:

**Proposition 3.2.** If \( \{ \varphi_i \}_{i=1}^M \) is a Parseval tight frame for \( \mathbb{H}_N \) and \( M < 2N \), then the only tight dual frame for \( \{ \varphi_i \}_{i=1}^M \) is \( \{ \varphi_i \}_{i=1}^M \) itself. If \( M \geq 2N \) then there are infinitely many (nonequivalent) tight alternate dual frames for \( \{ \varphi_i \}_{i=1}^M \).

**Proof.** (Proposition 3.2). With the notation of the proof of Proposition 3.1, the only change is that, since the dual frame is only tight and not Parseval tight, there is a frame bound \( A > 0 \) so that
\[
\| F_2 f \|^2 = A \| f \|^2, \quad \text{for all } f \in \mathbb{H}.
\]
Hence, as in the proof of Proposition 3.1 we have
\[
\| f \|^2 = \| F_1 f \|^2 = \| F_2 f \|^2 + \| (F_1 - F_2) f \|^2 = A \| f \|^2 + \| (F_1 - F_2) f \|^2.
\]
Hence, \( \| (F_1 - F_2) f \|^2 = (1 - A) \| f \|^2 \) for all \( f \in \mathbb{H} \). Hence, either \( F_1 - F_2 = 0 \) and \( A = 1 \) which gives us the PTF as in the previous proposition, (and so \( \varphi_i = \psi_i \) for all \( 1 \leq i \leq M \) or \( 1/\sqrt{1 - A} \langle F_2 - F_1 \rangle \) is an isometry on \( \mathbb{H}_N \). In the latter case it follows that \( \dim (F_1 \mathbb{H}_N) = N \), and so \( M \geq 2N \). Thus, if \( M < 2N \), the only tight dual frame is the frame itself.

On the other hand, if \( M \geq 2N \) given any \( F : \mathbb{H}_N \to \ell_2^M \) which is a constant times an isometry, and with \( F_1 \mathbb{H}_N \perp F \mathbb{H}_N \), \( F_1 + F \) defines a tight frame which is an alternate dual frame for \( \{ \varphi_i \} \). □

However, since it is really the equal-norm case we are interested in,

**Proposition 3.3.** Let \( M = 2N \) and let \( \{ \varphi_i \}_{i=1}^M \) be a Parseval tight frame for \( \mathbb{H}_N \) with analysis frame operator \( F_1 : \mathbb{H}_N \to \ell_2^M \). If there is an isometry \( F : \mathbb{H}_N \to \ell_2^M \) with \( F_1 \mathbb{H}_N \perp F \mathbb{H}_N \) and \( F_i e_i \perp F^* e_i \), for all \( 1 \leq i \leq M \), then \( \{ \varphi_i \}_{i=1}^M \) has infinitely many equal-norm tight alternate dual frames.

**Proof.** (Proposition 3.3). Again we use the notation of the proof of Proposition 3.1. Let \( F_2 = a F \), where \( a \neq 0 \). Then \( F_1 + F_2 \) defines a tight alternate dual frame for \( \{ \varphi_i \}_{i=1}^M \), say \( \psi_i = (F_1^* + F_2^* ) e_i \), for all \( 1 \leq i \leq M \). We just need to check that this frame is equal-norm. Let \( P : \ell_2^M \to F_1 \mathbb{H}_N \) be the orthogonal projection, so that \( P e_i = F_1 \varphi_i \), for all \( 1 \leq i \leq M \). It follows that \( \| P e_i \|^2 = N/M \) and \( \| (I - P) e_i \|^2 = 1 - N/M \), for all \( 1 \leq i \leq M \). Now,
\[
\psi_i = F_1^* e_i + F_2^* e_i = \varphi_i + F_2^* (I - P) e_i.
\]
Also, there is an \( a > 0 \) so that for every \( 1 \leq i \leq M \) we have
\[
\| \psi_i \|^2 = \| \varphi_i \|^2 + \| F_2^* (I - P) e_i \|^2 = \frac{N}{M} + a \| (I - P) e_i \|^2
\]
$$= \frac{N}{M} + a \left( 1 - \frac{N}{M} \right) = a + \left( 1 - a \right) \frac{N}{M}. $$

Hence, \( \{ \psi_k \}_{k=1}^M \) is an equal-norm tight frame. \qed

It can be shown that the results of this section actually classify when PTFs or ENPTFs have tight (respectively equal-norm tight) alternate dual frames, that is, all tight alternate dual frames for \( \{ \varphi_i \} \) are obtained by the methods of this section. We do not know in general which frames (not tight) have tight (respectively equal-norm tight) alternate dual frames.

### 3.4. Frames Equivalent to ENTFs

Another approach to the classification of ENTFs looks into sets of frames obtained from an ENTF by equivalence relations. For example, we know that every frame is equivalent to a Parseval tight frame. That is, given any frame \( \{ \varphi_i \}_{i \in I} \) with the frame operator \( S \), the frame \( \{ S^{-1/2} \varphi_i \}_{i \in I} \) is a Parseval tight frame which is equivalent to \( \{ \varphi_i \}_{i \in I} \). Therefore, it is natural to try to find ways to turn frames into equal-norm Parseval tight frames. As it turns out, this is not possible in most cases:

**Theorem 3.6.** If a frame \( \{ \varphi_i \}_{i \in I} \) with the frame operator \( S \) is equivalent to an ENTF, then \( \{ S^{-1/2} \varphi_i \}_{i \in I} \) is an ENPTF. In particular, a tight frame which is not equal-norm cannot be equivalent to any ENPTF.

**Proof.** (Theorem 3.6). It is known that \( \{ S^{-1/2} \varphi_k \} \) is a Parseval tight frame which is equivalent to \( \{ \varphi_k \} \). So if \( \{ \varphi_k \} \) is equivalent to an equal-norm tight frame, say \( \{ \psi_k \} \), and \( \| \psi_k \| = c \), for all \( k \), then \( \{ S^{-1/2} \varphi_k \} \) is equivalent to \( \{ \psi_k \} \). That is, there is an invertible operator \( T \) on \( \mathbb{H} \) so that \( TS^{-1/2} \varphi_k = \psi_k \).

Now we show that \( T/\sqrt{A} \) is a unitary operator. Let \( A \) be the tight frame constant of \( \{ TS^{-1/2} \varphi_k \} \). Then for all \( f \in \mathbb{H} \), the tightness of \( \{ TS^{-1/2} \varphi_k \} \) implies

$$A \| f \|^2 = \sum_k |\langle f, TS^{-1/2} \varphi_k \rangle|^2 = \sum_k |\langle T^* f, S^{-1/2} \varphi_k \rangle|^2. \quad (26)$$

However, since \( \{ S^{-1/2} \varphi_k \} \) is a PTF, then this leads us to

$$\sum_k |\langle T^* f, S^{-1/2} \varphi_k \rangle|^2 = \| T^* f \|^2. \quad (27)$$

Equating (26) and (27), we get that

$$A \| f \|^2 = \| T^* f \|^2,$$

that is, \( T/\sqrt{A} \) is unitary. Hence, the frame

$$S^{-1/2} \varphi_k = T^{-1} \psi_k,$$

is an ENPTF since

$$\| T^{-1} \psi_k \| = \frac{1}{\sqrt{A}} \| \psi_k \| = \frac{1}{\sqrt{A}} c, \quad \text{for all } k = 1, \ldots, M.$$
4. EQUAL-NORM TIGHT FRAMES WITH GROUP STRUCTURE

In this section, we examine frames which are generated by a group of unitary operators applied to a fixed vector in the Hilbert space. These classes are especially important in applications. The traditional use of one of these classes is in the Gabor frames used in signal/image processing. These are groups with two generators. There is also a class of wavelet frames which has two generators [9]. Recently, several new applications have arisen. In [25], the authors proposed using the redundancy of frames to mitigate the losses in packet-based communication systems such as the Internet. In [17], frames are used for multiple antenna coding/decoding (see the discussion Section 4.3 for further explanation). In [22, 12], connections between quantum mechanics and tight frames are established. Although each of these applications requires a different class of ENPTFs, they all have one important common constraint. Namely, calculations for the frame must be easily implementable on the computer. Since ENPTFs generated by a group of unitary operators satisfy this constraint, this class is one of the most important to understand.

In this section we will show that up to unitary equivalence, the ENPTFs generated by the set \( \{ U^k \varphi_0 \}_{k=0}^{M-1} \) (where \( U \) is unitary and \( \varphi_0 \in \mathbb{H} \)) are precisely the GHTFs. We then extend our discussion to ENPTFs generated by \( \{ U^k V \varphi_0 \} \) and higher numbers of generators. In the discussion Section 4.3 we will relate the results of this section to the literature.

4.1. ENTFs with a Single Generator

Here, we give a complete classification of ENPTFs of the form \( \{ U^k \varphi_0 \}_{k=0}^{M-1} \) where \( U \) is a unitary operator on \( \mathbb{H}_N \). We will, in fact, find that in this case \( \{ U^k \}_{k=0}^{M-1} \) must be a group. Moreover, we will see that the GHTFs will be that special class.

Since the proofs of the following results are long, the reader can find them in the Appendix. Our first result classifies GHTFs as those frames generated by powers of a special class of unitary operators applied to a fixed vector in \( \mathbb{H} \).

**Proposition 4.1.** There is a unitary operator \( V \) on \( \mathbb{H}_N \) with \( \varphi_k = V \psi_k \) and \( \{ \psi_k \}_{k=0}^{M-1} \) is a general harmonic frame for \( \mathbb{H}_N \), if and only if there is a vector \( \varphi_0 \in \mathbb{H}_N \) with \( || \varphi_0 ||^2 = \frac{N}{M} \), an orthonormal basis \( \{ e_i \}_{i=1}^{N} \) for \( \mathbb{H}_N \) and a unitary operator \( U \) on \( \mathbb{H}_N \) with \( U e_i = c_i e_i \), with \( \{ c_i \}_{i=1}^{N} \) distinct \( M \)th roots of some \( |c| = 1 \) so that \( \varphi_k = U^k \varphi_0 \), for all \( 0 \leq k \leq M - 1 \).

**Proof.** See Appendix A.1.

We now show that the only ENPTFs with group structure and a single generator are GHTFs. This result is an excellent result and a disappointment at the same time. On the one hand, the fact that GHTFs are the only ones with such a group structure proves once more why they are so universally used. It also spares us the trouble of looking for other such ENPTFs. On the other hand, we cannot find any other useful sets via this route as we were hoping for. Another important property of GHTFs (Theorem 4.2 from [25]) is that GHTFs are robust to the maximum number
of possible erasures, that is, a GHF with $M$ elements in $\mathbb{H}_N$ is robust to $e$ erasures for any $e \leq (M - N)$.

Our next theorem completes the classification of GHFs as being unitarily equivalent to those ENPTFs of the form $\{U^k \varphi_0\}_{k=0}^{M-1}$ where $U$ is a unitary operator on $\mathbb{H}$. As a consequence, we discover that, in this case, $\{U^k \varphi_0\}_{k=0}^{M-1}$ is a group.

**Theorem 4.1.** Let $U$ be a unitary operator on $\mathbb{H}_N$, $\varphi_0 \in \mathbb{H}_N$ and assume
\[
\{U^k \varphi_0\}_{k=0}^{M-1}
\]
\text{is an ENPTF for $\mathbb{H}_N$.} Then $U^M = cI$ for some $|c| = 1$ and $\{U^k \varphi_0\}_{k=0}^{M-1}$ is a general harmonic frame. That is, the GHFs are the only frames unitarily equivalent to ENPTFs generated by a group of unitary operators with a single generator.

**Proof.** See Appendix A.2. ■

### 4.2. ENPTFs with Two or More Generators

Having completely characterized ENPTFs which come from a group of unitary operators with one generator, we now turn our attention to those with more than one. The fundamental examples of frames with two generators are the Gabor frames $\{E_{m,T} g\}_{m,n \in \mathbb{Z}}$ (or, in our case, the finite discrete Gabor frames). Each of these frames is equivalent to the ENPTF Gabor frame $\{E_{m,T} S^{-1} g\}_{m,n \in \mathbb{Z}}$ where $S$ is the frame operator for $\{E_{m,T} g\}_{m,n \in \mathbb{Z}}$.

We will classify the ENPTFs of the form $\{U^i V^j \varphi_0\}_{i=0}^{L-1}, j=0}^{M-1}$ where $\{V^j \varphi_0\}_{j=0}^{M-1}$ is an ENPTF for its span. In the process of proving these results, we introduce a general method for using special sets of finite-rank projections to produce frames for a space. If we associate a frame $\{\varphi_i\}_{i=1}^M$ with the set of rank-1 orthogonal projections $P_i$ taking $\mathbb{H}$ onto span $\varphi_i$, then we can view the results of this section as a generalization of the very notion of a frame to the case where the $P_i$ have arbitrary rank.

Our first result states that given a GHF generated by a unitary operator $V$, a unitary operator $U$ and an integer $M$, we can always find a corresponding ENPTF generated by $U, V$.

**Proposition 4.2.** Let $V$ be a unitary operator on $\mathbb{H}_N$, let $m \in \mathbb{N}$ and $\psi_0 \in H$ so that $\{V^j \psi_0\}_{j=0}^{M-1}$ is an ENPTF for $\mathbb{H}_N$. Then for every unitary operator $U$ on $\mathbb{H}_N$ and every $M \in \mathbb{N}$, there is a vector $\varphi_0 \in \mathbb{H}_N$ such that $\{U^k V^i \varphi_0\}_{i=0}^{M-1}$ is an equal-norm, Parseval tight frame for $\mathbb{H}_N$.

**Proof.** (Proposition 4.2). Let $\varphi_0 = \psi_0 / \sqrt{M}$. Now, for every $f \in \mathbb{H}_N$ we have
\[
\frac{1}{M} \sum_{k=0}^{M-1} |\langle f, U^k V^i \varphi_0 \rangle|^2 = \frac{1}{M} \sum_{k=0}^{M-1} \sum_{i=0}^{M-1} |\langle U^{-k} f, V^i \varphi_0 \rangle|^2 = \frac{1}{M} \sum_{k=0}^{M-1} \sum_{i=0}^{M-1} |\langle U^{-k} f, V^i \varphi_0 \rangle|^2.
\]

Since $\{V^i \psi_0\}_{i=0}^{M-1}$ is an ENPTF, the previous sum equals
\[
\frac{1}{M} \sum_{k=0}^{M-1} |\langle U^{-k} f \rangle|^2 = \frac{1}{M} \sum_{k=0}^{M-1} ||f||^2 = ||f||^2.
\]
■
It is easily seen that an invertible operator on \( H \) maps a frame for \( H \) to another frame for \( H \). As a consequence of Proposition 2.1, we can apply a unitary operator to any ENPTF and get a new ENPTF. If this unitary operator is part of the generating set for our ENPTF, then our new ENPTF has a special form as given in the next proposition.

**Proposition 4.3.** If \( U \) is unitary and \( \{ U^j \varphi_0 \} \) is an ENPTF for \( H_N \), then for every \( M \in \mathbb{Z} \) and for every \( f \in H_N \) we have,

\[
f = \sum_{k,j} \langle f, U^{k+M} V^j \varphi_0 \rangle U^{k+M} V^j \varphi_0,
\]

that is, \( \{ U^{k+M} V^j \varphi_0 \}_{k,j} \) is an ENPTF as well.

**Proof (Proposition 4.3).** Since \( U^M \) is unitary and \( \{ U^j \varphi_0 \}_{k,j} \) is an ENPTF for \( H_N \), it follows that \( \{ U^M U^j \varphi_0 \}_{k,j} \) is also an ENPTF for \( H_N \).

To explain where we are going from here, let us revisit the notion of an ENPTF and look at it from a slightly different point of view. Suppose \( \{ \varphi_i \}_{i \in I} \) is an ENPTF for a (finite or infinite-dimensional) Hilbert space \( H \) with \( \| \varphi_i \| = 1 \), for all \( i \in I \). For each \( i \in I \), let \( P_i \) be the orthogonal projection of \( H \) onto the one-dimensional subspace of \( H \) spanned by \( \varphi_i \). Then, for all \( f \in H \)

\[
\sum_{i \in I} \| P_i f \|^2 = \sum_{i \in I} |\langle f, \varphi_i \rangle|^2 = \sum_{i \in I} |\langle f, \varphi_i \rangle|^2 = \sum_{i \in I} |\langle f, \varphi_i \rangle|^2 = c^2 \sum_{i \in I} |\langle f, \varphi_i \rangle|^2 = c^2 \| f \|^2.
\]

Conversely, let \( \{ P_i \}_{i \in I} \) be rank-1 orthogonal projections on \( H \) satisfying

\[
\sum_{i \in I} \| P_i f \|^2 = a \| f \|^2, \quad \text{for all } f \in H.
\]

Then \( \{ \varphi_i \}_{i \in I} \) is an ENPTF for \( H \) where \( \varphi_i \in P_i H \) and \( \| \varphi_i \|^2 = 1/a \). That is, if \( f \in H \) then

\[
\sum_{i \in I} |\langle f, \varphi_i \rangle|^2 = \sum_{i \in I} |\langle P_i f, \varphi_i \rangle|^2 = \sum_{i \in I} \| P_i f \|^2 \| \varphi_i \|^2 = \frac{1}{a} \sum_{i \in I} \| P_i f \|^2 = \frac{1}{a} a \| f \|^2 = \| f \|^2.
\]

It follows that the condition on \( \{ \varphi_i \} \) which guarantees that we have an ENPTF is really a condition on the rank-1 orthogonal projections of \( H \) onto the span of \( \varphi_i \). It is this which we now generalize to find our next general class of ENPTFs. Since this material is also new for general frames, we start here.

**Proposition 4.4.** Let \( \{ P_i \}_{i \in I} \) be a set of projections (of any rank) on a (finite or infinite-dimensional) Hilbert space \( H \) and assume there are constants \( 0 < A, B \)
satisfying,
\[ A\| f \|^2 \leq \sum_{i \in I} \| P_i f \|^2 \leq B\| f \|^2, \quad \text{for all } f \in \mathbb{H}. \]

For each \( i \in I \), let \( \{ \varphi_{ij} \}_{j=1}^{M_i} \) be a frame for \( P_i \mathbb{H} \) with frame bounds \( A_i, B_i \). Then \( \{ \varphi_{ij} \}_{j=1, i \in I} \) has frame bounds,
\[ A \left( \inf_{i \in I} A_i \right), \quad B \left( \sup_{i \in I} B_i \right). \]

**Proof.** For any \( f \in \mathcal{H} \) we have
\[
\sum_{j=1, i \in I}^{M_i} |(f, \varphi_{ij})|^2 = \sum_{i \in I} \sum_{j=1}^{M_i} |(f, \varphi_{ij})|^2
\]
\[
= \sum_{i \in I} \sum_{j=1}^{M_i} |(P_i f, \varphi_{ij})|^2 \leq \sum_{i \in I} B_i \| P_i f \|^2
\]
\[
\leq \sup_{i \in I} B_i \sum_{i \in I} \| P_i f \|^2 \leq \left( \sup_{i \in I} B_i \right) B \| f \|^2.
\]

The lower frame bound is computed similarly. \( \blacksquare \)

The cases of interest to us are the next two corollaries: the first for PTFs and the second for ENPTFs.

**Corollary 4.1.** Let \( \{ P_i \}_{i \in I} \) be a set of projections on a Hilbert space \( \mathbb{H} \) satisfying:
\[
\sum_{i \in I} \| P_i f \|^2 = a^2 \| f \|^2, \quad \text{for all } f \in \mathbb{H}.
\]

Then \( a \geq 1 \), and if, for all \( i \in I \), \( \{ \varphi_{ij} \}_{j=1}^{M_i} \) is a PTF for \( P_i \mathbb{H} \), then \( \{ \frac{1}{a} \varphi_{ij} \}_{j=1, i \in I}^{M_i} \) is a PTF for \( \mathbb{H} \).

In the next corollary we assume that the projections \( P_i \) all have the same rank and the frames for \( P_i \mathbb{H} \) all have the same number of elements. This assumption is necessary to guarantee that our frame is equal-norm. That is, as we observed in Section 2.3, if \( \dim P_i \mathbb{H} = N \) and \( \{ \varphi_{ij} \}_{j \in J} \) is an ENPTF for \( P_i \mathbb{H} \) then
\[
\| \varphi_{ij} \|^2 = \frac{N}{|J|}.
\]

**Corollary 4.2.** Let \( \{ P_i \}_{i \in I} \) be a sequence of projections (all with the same rank) on a Hilbert space \( \mathbb{H} \) satisfying:
\[
\sum_{i \in I} \| P_i f \|^2 = a^2 \| f \|^2, \quad \text{for all } f \in \mathbb{H}.
\]

Then \( a \geq 1 \), and if, for all \( i \in I \), \( \{ \varphi_{ij} \}_{j \in J} \) is an ENPTF for \( P_i \mathbb{H} \), then \( \{ \frac{1}{a} \varphi_{ij} \}_{j \in J, i \in I} \) is an ENPTF for \( \mathbb{H} \).

We are now ready to consider ENPTFs with two generators.
Theorem 4.2. Let $U$ be a unitary operator on $\mathbb{H}$, and let $\{U^j\varphi_0\}_{j=0}^{M-1}$ be an ENTF (with tight frame bound $1/a$) for its closed linear span in $\mathbb{H}$. Let $P_0$ be the orthogonal projection of $\mathbb{H}$ onto this span. Assume that $\{U^j V^i \varphi_0\}_{i=0, j=0}^{L-1, M-1}$ is an ENPTF for $\mathbb{H}$. If $P_i$ is the orthogonal projection of $\mathbb{H}$ onto the span of $U^i P_0 \mathbb{H}$, for all $1 \leq i \leq L - 1$, then

$$\sum_{i=0}^{L-1} \|P_i f\|^2 = a\|f\|^2, \text{ for all } f \in \mathbb{H}.$$ 

Proof. Note that for all $1 \leq i \leq K - 1$ we have $P_i = U^i P_0 U^{-i}$. Now, for any $f \in \mathbb{H}$ we compute,

$$\sum_{i=0}^{L-1} \|P_i f\|^2 = \sum_{i=0}^{L-1} \|U^i P_0 U^{-i} f\|^2 = \sum_{i=0}^{L-1} \|P_0 U^{-i} f\|^2 = \sum_{i=0}^{L-1} a \sum_{j=0}^{M-1} |\langle U^{-i} f, V^j \varphi_0 \rangle|^2 = a \sum_{i=0}^{L-1} \sum_{j=0}^{M-1} |\langle f, U^i V^j \varphi_0 \rangle|^2 = a\|f\|^2.$$

The next theorem is the converse of the above.

Theorem 4.3. Let $\{P_i\}_{i=0}^{L-1}$ be a set of orthogonal projections on $\mathbb{H}$ satisfying

$$\sum_{i=0}^{L-1} \|P_i f\|^2 = a^2\|f\|^2, \text{ for all } f \in \mathbb{H}.$$ 

Assume that $U$ is a unitary operator on $\mathbb{H}$ so that $U^i P_0 \mathbb{H} = P_i \mathbb{H}$. Let $\varphi_0 \in P_0 \mathbb{H}$ and let $V$ be a unitary operator on $P_0 \mathbb{H}$ such that $\{V^j \varphi_0\}_{j=0}^{M-1}$ is an ENPTF for $P_0 \mathbb{H}$. Then $\{\frac{1}{a} U^i V^j \varphi_0\}_{i=0, j=0}^{L-1, M-1}$ is an ENPTF for $\mathbb{H}$.

Proof. For all $f \in \mathbb{H}$ we have,

$$\sum_{i=0}^{L-1} \sum_{j=0}^{M-1} |\langle f, \frac{1}{a} U^i V^j \varphi_0 \rangle|^2 = \frac{1}{a^2} \sum_{i=0}^{L-1} \sum_{j=0}^{M-1} |\langle U^{-i} f, V^j \varphi_0 \rangle|^2 =$$

$$\frac{1}{a^2} \sum_{i=0}^{L-1} \|P_0 U^{-i} f\|^2 = \frac{1}{a^2} \sum_{i=0}^{L-1} \|U^i P_0 U^{-i} f\|^2 = \frac{1}{a^2} \sum_{i=0}^{L-1} \|P_i f\|^2 = \|f\|^2.$$

4.3. Discussion

Some remarks are in order:
1. The assumptions in Theorems 4.2 and 4.3 that \( \{ V^{j} \varphi_{0} \}_{j=0}^{M-1} \) is an ENPTF for its span is sufficient for the conclusion of the theorems but not necessary. For example, it is known to Gabor frame specialists that for \( ab < 1 \), there are Gabor frames \( \{ E_{m} T_{n} g \}_{m,n \in \mathbb{Z}} \) for which neither of \( \{ E_{m} T_{n} g \}_{m \in \mathbb{Z}} \) nor \( \{ E_{m} T_{n} g \}_{n \in \mathbb{Z}} \) is a frame for its closed linear span. The equivalent ENPTF Gabor frame \( \{ E_{m} T_{n} S^{-1/2} g \}_{m,n \in \mathbb{Z}} \) fails the hypotheses of Theorems 4.2 and 4.3 but satisfies the conclusion.

2. The results of Section 4.2 generalize to three or more generators. For example, for three generators, Theorem 4.3 becomes:

**Theorem 4.4.** Let \( U, V \) be unitary operators with \( \{ U^{i} V^{j} \varphi_{0} \}_{i=0, j=0}^{L-1, M-1} \) a ENPTF for its span. Let \( P_{0} \) be the projection of the Hilbert space \( H \) onto this span. Let \( W \) be a unitary operator on \( H \) so that

\[
\sum_{k=0}^{K-1} ||W^{k} P_{0} W^{-k} f||^{2} = a^{2} ||f||^{2}, \quad \text{for all } f \in \mathbb{H}.
\]

Then \( \{ \frac{1}{a} W^{k} U^{i} V^{j} \varphi_{0} \}_{i=0, j=0}^{L-1, M-1} \) is an ENPTF for \( \mathbb{H} \).

3. It would be very interesting to classify when a finite group of unitaries \( G \) generates an ENPTF for \( \mathbb{H} \) of the form \( \{ U \varphi_{0} \}_{U \in G} \). Since finite Abelian groups are isomorphic to a direct product of cyclic groups, the results of this section give sufficient conditions for \( \{ U \varphi_{0} \}_{U \in G} \) to generate an ENPTF for \( \mathbb{H} \). Frames generated by Abelian groups of unitaries were studied in [4] where they are called **geometrically equal-norm frames** (GU frames). It is shown there that the canonical dual frame of a GU frame is also a GU frame and that the equivalent PTF frame is also GU. Since GU frames have strong symmetry properties, they are particularly useful in applications. In [4], it is further shown that the frame bounds resulting from removing a single vector of a GU frame are the same regardless of the particular vector removed. This result for HTFs was observed in [25].

4. Frames generated by possibly noncommutative groups of unitaries are important in multiple antenna coding and decoding [17]. Here, one needs classes of unitary space-time signals (that is, frames generated by classes of unitary operators) called **constellations**. It is also desirable in this setting to have full transmitter diversity, meaning that

\[
\det (I - U) \neq 0, \quad \text{for all } I \neq U \in G.
\]

Groups with this property are called **fixed-point free groups**. In a tour-de-force, the authors in [17] classify all full-diversity constellations that form a group, for all rates and numbers of transmitting antennas. Along the way they correct some errors in the classification theory of fixed point free groups.

5. **Classification of Equal-Norm Tight Frames with Erasures**

As mentioned in the introduction, one of the main applications that motivated us to examine equal-norm tight frames is that of robust data transmission. This means
that at some point, the system experiences losses. These losses are modeled as erasures of transmitted frame coefficients. Since at the receiver side, this looks like the original frame was the one without vectors corresponding to erased coefficients, we examine the structure of our frames after losses.

The first question is whether after erasures what we have is still a frame? For the MB frame, if we erase any one element, the remaining two are enough for reconstruction. However, if we erase any two, we have lost one subspace and reconstruction is not possible. We can provide more robustness by adding more vectors. For example, take a equal-norm tight frame in $\mathbb{R}^2$ made up of two orthonormal bases $(1,0),(0,1),(-1,0),(0,-1)$. This frame is robust to any one erasure; what is left contains at least one of the two bases. However, if two elements are erased, the situation is not that clear anymore. We could erase coefficients corresponding to one of the bases and still have a basis able to reconstruct. If, on the other hand, we lose coefficients corresponding to two collinear vectors, we are stuck; we have lost one entire subspace and cannot reconstruct. We could, however, take another ENPTF with $M = 4$ vectors in $\mathbb{R}^2$ - the HTF with the analysis frame operator

$$F = \begin{pmatrix}
1 & 0 \\
\sqrt{2}/2 & \sqrt{2}/2 \\
0 & 1 \\
-\sqrt{2}/2 & \sqrt{2}/2
\end{pmatrix}.$$  

This frame is also made up of two orthonormal bases. However, this frame is robust to any two erasures. It is thus more robust than the MB frame; we pay for this added benefit with more redundancy (more vectors). It is also more robust than the previous frame with 4 vectors.

These simple examples demonstrate the types of questions we will be asking in this section. One might think that starting with a tight frame might provide some resilience to losses (as opposed to starting with a general frame). As we have seen in our example, this is not the case. Thus, we are searching for frames robust to a certain number of erasures. That is, frames which remain frames after erasures. There are frames on $\mathbb{H}_N$ with $M$ elements which are robust to $M - N$ erasures, namely the HTFs (Theorem 4.2 from [25]). Such frames are the best. This is clearly optimal since any more erasures would not leave enough elements to span $\mathbb{H}_N$. In this section, we will characterize frames based on their robustness to erasures.

### 5.1. ENTFs and ENPTFs Robust to One Erasure

In this section we will consider ENPTF which are robust to one erasure. This contains the basic idea for the general case.

We start with the notion of a frame robust to $k$ erasures, or a $k$-robust frame.

**Definition 5.1.** A frame $\{\varphi_i\}_{i=1}^M$ is said to be robust to $k$ erasures if $\{\varphi_i\}_{i \in I^c}$ is still a frame, for $I$ any index set of $k$ erasures, $I \subset \{1, 2, \cdots, M\}$ and $|I| = k$.

The following property tells us we do not destroy the robustness of the frame by projection. This observation lead us to the idea that we could classify frames by starting from a large space and "step down" using projections. For example, we could start with a frame robust to one erasure and step down to frames (hopefully) robust to two erasures, then once more to frames robust to three erasures and so
on. Although this will not be the case, the idea of stepping down lead us to the results in this section.

Note that it is clear from the definition of a frame that if we apply an orthogonal projection \( P \) on \( \mathbb{H} \) to a frame we will get a frame for \( P\mathbb{H} \) with the same frame bounds.

**Proposition 5.1.** Let \( \{\varphi_i\}_{i=1}^M \) be a frame in \( \mathbb{H}_N \) robust to \( k \) erasures and let \( P \) be an orthogonal projection on \( \mathbb{H}_N \). Then \( \{P\varphi_i\}_{i=1}^M \) is a frame for \( P\mathbb{H}_N \) robust to \( k \) erasures.

**Proof.** Let \( I \) be the index set of erasures, \( I \subset \{1, 2, \cdots, M\} \) with \( |I| = k \). Now, \( \{\varphi_i\}_{i \in I} \) spans \( \mathbb{H}_N \) and so \( \{P\varphi_i\}_{i \in I} \) is a frame for \( P\mathbb{H}_N \) with the same frame bounds. ■

The main ingredient for classifying frames robust to one erasure is contained in the next proposition.

**Proposition 5.2.** Let \( \{\varphi_i\}_{i=1}^M \) be a set of vectors in \( \mathbb{H}_N \). The following are equivalent:

1. \( \{\varphi_i\}_{i=1}^M \) is a frame robust to one erasure.
2. There are nonzero scalars \( a_i \neq 0 \), for \( 1 \leq i \leq M \) so that

\[
\sum_{i=1}^{M} a_i \varphi_i = 0.
\]

**Proof.** (1) \( \Rightarrow \) (2): Choose \( I \subset \{1, 2, \cdots, M\} \) maximal for which there are nonzero \( a_i \)'s, \( i \in I \) and

\[
g = \sum_{i \in I} a_i \varphi_i = 0.
\]

We claim that \( |I| = M \). We proceed by contradiction. If \( I \neq \{1, 2, \cdots, M\} \), choose \( m \in I^c \). Since \( \{\varphi_i\}_{i=1}^M \) is robust to one erasure, there are scalars \( \{b_i\} \), not all zero, so that if \( \varphi_m \) is erased, it can be recovered from the rest as

\[
\varphi_m = \sum_{i \neq m} b_i \varphi_i,
\]

or

\[
h = \varphi_m - \sum_{i \in I} b_i \varphi_i - \sum_{m \neq i \in I^c} b_i \varphi_i = 0.
\]

We have two cases:

**Case 1:** Assume that \( b_i = 0 \) for all \( i \in I \).

Then, \( h = \varphi_m - \sum_{m \neq i \in I^c} b_i \varphi_i = 0 \). In this case, \( g + h = 0 \) and has nonzero coefficients on every \( \varphi_i, i \in I \), plus a nonzero coefficient on \( \varphi_m \) contradicting the maximality of \( I \).
Case II: At least one \( b_i \neq 0 \) for some \( i \in I \).

Since \( a_i \neq 0 \) for all \( i \in I \), we can choose an \( \epsilon > 0 \) so that

\[
\epsilon \neq a_i/b_i, \quad \text{for all } i \in I.
\]

Now, \( g + \epsilon h = 0 \) and has nonzero coordinates on \( \varphi_i \), for all \( i \in I \), as well as \( \epsilon \) for a coordinate on \( \varphi_m \), again contradicting the maximality of \( I \).

(2) \( \Rightarrow \) (1): Assume \( a_i \neq 0 \), for all \( 1 \leq i \leq M \) and

\[
\sum_{i \in I} a_i \varphi_i = 0.
\]

Then for each \( m \in I \) we have:

\[
\varphi_m = - \sum_{m \neq i \in I} \frac{a_i}{a_m} \varphi_i,
\]

that is, any vector lost can be recovered using the rest and so \( \{ \varphi_i \}_{i=1}^M \) is robust to the erasure of \( \varphi_m \), for an arbitrary \( m \in I \).

Note that to construct a frame guaranteed not to be robust to one erasure, it is enough to put one vector, say \( \varphi_M \), orthogonal the span of the rest. Erasing that vector destroys the frame property. Thus, we cannot find a nonzero coefficient \( a_M \) such that \( \sum_{i=1}^M a_i \varphi_i = 0 \).

For example, we know that the MB frame \( \{ \varphi_i \}_{i=1}^3 \) is robust to one erasure (Theorem 4.1 from [25]). Hence, we can find \( a_1 = a_2 = a_3 = 1 \) such that \( \sum_{i=1}^3 a_i \varphi_i = 0 \).

The next results will characterize frames robust to one erasure. Since we mentioned the idea of stepping down, we will start from an orthonormal basis \( \{ e_i \}_{i=1}^M \) for \( \mathbb{H}_M \) and project it using a projection operator \( P \) or \( I - P \). We thus look into a few facts connecting \( P \) and \( I - P \).

1. If \( P \) is an orthogonal projection, then \( (I - P) \) is an orthogonal projection as well.

2. The subspaces \( P \) and \( (I - P) \) project onto are orthogonal. For any \( f \in \mathbb{H}_M \),

\[
\langle (I - P)f, Pf \rangle = \langle P^*(I - P)f, f \rangle = \langle (P - P)f, f \rangle = 0.
\]

3. \( \{ (I - P)e_i \}_{i=1}^M \) is equal-norm if and only if \( \{ Pe_i \}_{i=1}^M \) is equal-norm. To see this we compute, for all \( i, j \)

\[
\langle (I - P)e_i, (I - P)e_j \rangle = \langle (I - P)e_j, (I - P)e_j \rangle
\]

\[
\langle (I - P^*)(I - P)e_i, e_j \rangle = \langle (I - P^*)(I - P)e_j, e_j \rangle
\]

\[
\langle (I - P)e_i, e_i \rangle = \langle (I - P)e_j, e_j \rangle
\]

\[
1 - \langle Pe_i, e_i \rangle = 1 - \langle Pe_j, e_j \rangle
\]

\[
\langle P^* Pe_i, e_i \rangle = \langle P^* Pe_j, e_j \rangle
\]

\[
\langle Pe_i, Pe_i \rangle = \langle Pe_j, Pe_j \rangle.
\]

Here we used the fact that \( P \) is an orthogonal projection and thus \( P = P^2 = P^* P \).
4. Both \( \{ Pe_i \}_{i=1}^{M} \) and \( \{(I - P)e_i\}_{i=1}^{M} \) are PTFs.

By Theorem 2.1, all PTFs are of the form \( \{ Pe_i \}_{i=1}^{M} \), where \( \{ e_i \}_{i=1}^{M} \) is an orthonormal basis for \( \mathbb{H} \) and \( P \) is an orthogonal projection on \( \mathbb{H} \). The ENPTFs form a subclass of these frames. In the rest of this paper we will identify this subclass. So we will be working with frames of the form above. We will discover that the subspace \( P\mathbb{H} \) determines when the frame is an ENPTF. From our earlier discussion, if \( P \) is an orthogonal projection on \( H \), we may work either with \( \{ Pe_i \} \) or \( \{(I - P)e_i\} \) to classify ENPTFs. We will freely switch between these classes because each of them has certain advantages for specific results. The class \( \{ Pe_i \} \) works well for classifications when the dimension of \( P\mathbb{H} \) is "large" relative to the dimension of \( \mathbb{H} \). On the other hand, \( \{(I - P)e_i\} \) is easier to work with when the dimension of \( P\mathbb{H} \) is "small" relative to the dimension of \( \mathbb{H} \). Also, as we will see, important information about \( \{ Pe_i \} \) is often contained in \( (I - P)\mathbb{H} \) (and vice-versa). So we will need to bring both of these into our discussion.

Now we give the general classification for frames robust to one erasure.

**Corollary 5.1.** Let \( \{ e_i \}_{i=1}^{M} \) be an orthonormal basis for \( \mathbb{H}_M \) and let \( P \) be an orthogonal projection on \( \mathbb{H}_M \). The following are equivalent:

1. \( \{(I - P)e_i\}_{i=1}^{M} \) is a frame robust to one erasure.
2. There are nonzero scalars \( a_i \neq 0 \), for \( 1 \leq i \leq M \) so that
   \[
   \sum_{i=1}^{M} a_i (I - P)e_i = 0.
   \]
3. There is an \( f \in \text{span}_{1 \leq i \leq M} Pe_i \) so that
   \[
   \langle f, e_i \rangle \neq 0, \quad \text{for all } 1 \leq i \leq M.
   \]

**Proof.** The equivalence of (1) and (2) comes from Proposition 5.2. Let us check the equivalence of (2) and (3).

(2) \( \Rightarrow \) (3): Given (2), choose \( f \) to be

\[
 f = \sum_{i=1}^{M} a_i e_i.
\]

By our assumption, \( \sum_{i=1}^{M} a_i e_i = \sum_{i=1}^{M} a_i Pe_i \) and thus

\[
 f = \sum_{i=1}^{M} a_i Pe_i \in P\mathbb{H}_M.
\]

Moreover, \( \langle f, e_i \rangle = a_i \neq 0 \), for all \( 1 \leq i \leq M \).

(3) \( \Rightarrow \) (2): Choose \( f \in P\mathbb{H}_M \) as in (3) and call \( a_i = \langle f, e_i \rangle \neq 0 \), for all \( 1 \leq i \leq M \). Now

\[
 \sum_{i=1}^{M} a_i (I - P)e_i = \sum_{i=1}^{M} \langle f, e_i \rangle (I - P)e_i = \sum_{i=1}^{M} \langle f, e_i \rangle e_i - \sum_{i=1}^{M} \langle Pf, e_i \rangle e_i = 0,
\]
since $f \in P\mathbb{H}_M$, and thus $Pf = f$. □

Corollary 5.1 classifies frames which are robust to one erasure. We now extend this to a classification of ENPTFs robust to one erasure.

**Corollary 5.2.** Let $\{e_i\}_{i=1}^M$ be an orthonormal basis for $\mathbb{H}_M$ and let $P$ be an orthogonal projection on $\mathbb{H}_M$. The following are equivalent:

1. $\{(I - P)e_i\}_{i=1}^M$ is a frame robust to one erasure.
2. There is a $g = \sum_{i=1}^M a_i e_i$ with nonzero scalars $a_i \neq 0$, for all $1 \leq i \leq M$ such that $Pf = (f, g)g$, for all $f \in \mathbb{H}_M$, and $\|g\| = 1$.

Moreover, if $P$ is rank-1, $\{(I - P)e_i\}_{i=1}^M$ is a equal-norm frame if and only if $|a_i| = 1/\sqrt{M}$, for all $1 \leq i \leq M$.

**Proof.** (1) $\Leftrightarrow$ (2) is immediate from Corollary 5.1.

For the moreover part, we know that $\{(I - P)e_i\}_{i=1}^M$ is equal-norm if and only if $\{Pe_i\}_{i=1}^M$ is equal-norm. Also, since $P$ is rank-1, for all $1 \leq i \leq M$ and using the expression $Pf = (f, g)g$ in Part 2, with $f = e_i$ we have,

$$Pe_i = a_i g.$$  

Hence, $\|Pe_i\| = \|Pe_j\|$ is true if and only if $|a_i| = |a_j|$, for all $1 \leq i, j \leq M$. That is, $\{Pe_i\}_{i=1}^M$ is equal-norm (and hence $\{(I - P)e_i\}_{i=1}^M$ is equal-norm) if and only if $|a_i| = |a_j|$, for all $1 \leq i, j \leq M$. Finally, $\|Pe_i\| = |a_i|\|g\| = |a_i| = 1/\sqrt{M}$. □

### 5.2. ENPTFs Robust to More than One Erasure

We now try to apply the same ideas from the previous section to classify frames robust to more than one erasure. The classification of ENPTFs with $k$ erasures in this section is useful if we have $M$ vectors in an $N$-dimensional space and $M - N$ is “small”. In the next section we will give another classification of this set which works best when $M - N$ is “large”.

In what follows, $I \subset \{1, 2, \cdots, M\}$ will denote the erasure index set.

**Proposition 5.3.** Let $\{e_i\}_{i=1}^M$ be an orthonormal basis for $\mathbb{H}_M$. Let $P$ be an orthogonal projection of $\mathbb{H}_M$ onto an $L$-dimensional subspace $\mathbb{H}_L$. Fix $I \subset \{1, 2, \cdots, M\}$ with $|I| = k \leq L$ and let $K = \text{span}_{i \in I}e_i$. If $\{\varphi_j\}_{j=1}^L$ is any orthonormal basis for $\mathbb{H}_L$ and we have the following $L \times M$ matrix

$$A = (\varphi_j, e_i) \quad j = 1, \cdots, L, \quad i = 1, \cdots, M,$$

then

$$\dim \ker (I - P)|_K = L - \text{row rank of the k columns of A indexed by I}.$$  

**Proof.** We have

$$\ker (I - P)|_K = \{ f \in K | (I - P)f = 0 \} = \ker (I - P) \cap K.$$
Now, apply row reduction (relative to \( \{ e_i \}_{i=1}^{M} \)) to \( \{ \varphi_i \}_{i=1}^{L} \) using the elements of the columns in \( I \). This gives a linearly independent set \( \{ g_j \}_{j=1}^{L} \cup \{ g_j \}_{j=s+1}^{L} \) spanning \( K \) with
\[
s = \text{row rank of } (\langle \varphi_j, e_i \rangle)_{j=1, i \in I}^L,
\]
given \( g_j \in K \) for \( s + 1 \leq j \leq L \) and
\[
(\text{span}_{1 \leq j \leq s} g_j) \cap K = 0.
\]
Hence,
\[
\ker (I - P) \cap K = \text{span}_{s+1 \leq i \leq L} e_i.
\]
Therefore,
\[
\dim (\ker (I - P)) \cap K = \dim (\ker (I - P)|_K) = L - (s + 1) + 1 = L - s.
\]

We are looking for the PTFs which are robust to \( k \) erasures. Proposition 5.3 actually yields a stronger result. Namely, it gives necessary and sufficient conditions for \( \{ P e_i \} \) to be robust to one particular choice of \( k \) erasures. We state this stronger result in two different forms in the next two propositions.

**Proposition 5.4.** With the notation of Proposition 5.3, the following are equivalent:

1. \( \{ (I - P) e_i \}_{i=1}^{M} \) is robust to the erasure of the elements \( \{ (I - P) e_i \}_{i \in I} \).
2. We have rank \( (I - P)|_K = M - L \).
3. We have \( \dim [\ker (I - P)|_K] = L - k \).

**Proof.** (1) \( \Leftrightarrow \) (2): \( \{ (I - P) e_i \}_{i=1}^{M} \) is robust to the erasure of the elements \( \{ (I - P) e_i \}_{i \in I} \) if and only if \( (I - P)|_K \) is full rank, which must be rank \( (I - P) = M - L \).

(2) \( \Leftrightarrow \) (3): By Proposition 5.3,
\[
\dim (\ker (I - P)|_K) = L - \text{[row rank of the } \k \text{ columns of } A \text{ indexed by } I] \geq L - k.
\]
On the other hand, \( (I - P)|_K \) is full rank if and only if \( (I - P)(I - P_i) \) is full rank, where \( P_i \) is the orthogonal projection of \( \mathbb{R}_M \) onto \( \text{span}_{i \in I} e_i \). Hence,
\[
\dim (\ker (I - P)(I - P_i)) \leq L.
\]
But, \( e_i \in \ker (I - P_i) \), for all \( i \in I \). Hence,
\[
\dim (\ker (I - P)(I - P_i)) = \dim (\ker (I - P)) + k \leq L.
\]
Therefore,
\[
\dim (\ker (I - P)) \leq L - k.
\]
Proposition 5.4 gives precise information when a frame is robust to the erasure of one particular choice of \( k \) elements in terms of the coefficients of \( \{g_{i}\} \) relative to the unit vector basis of \( \mathbb{H}_k \). The following corollary is a statement for a fixed choice of erasures as well.

**Corollary 5.3.** With the notation of Proposition 5.3, the following are equivalent:

1. \( \{(I - P)e_i\}_{i=1}^M \) is robust to the erasure of the elements \( \{(I - P)e_i\}_{i \in I} \).
2. The row rank of \( \left\langle \langle \varphi_j, e_i \rangle \right\rangle_{j=1, i \in I}^L \) equals \( k \).

Applying the above result to every choice of erasures results in Theorem 5.1 and a classification of when our frame is robust to any \( k \) erasures. We are dealing here with general frames. We will deal with equal-norm frames right afterwards.

**Theorem 5.1.** With the notation of Proposition 5.3, the following are equivalent:

1. \( \{(I - P)e_i\}_{i=1}^M \) is robust to \( k \) erasures.
2. For every \( I \subset \{1, 2, \cdots M\} \) with \( |I| = k \), the row rank of \( A = \left\langle \langle \varphi_j, e_i \rangle \right\rangle_{j=1,i \in I}^L \) equals \( k \).

Note the crucial role played by erased elements in the theorem, since in the statement, the indices are from \( I \).

Next we see what it takes for such frames to be equal-norm. Here, we call the “angle” between two vectors the inner product when this is really the cosine of the angle. Note that this result classifies when \( \{(I - P)e_i\} \) is an ENPTF without any reference to erasures.

**Theorem 5.2.** With the notation of Proposition 5.3, the following are equivalent:

1. \( \{Pe_i\}_{i=1}^M \) is equal-norm (and hence \( \{(I - P)e_i\}_{i=1}^M \) is equal-norm).
2. For every \( 1 \leq i \leq M \) we have,

\[
(A^* A)_{ii} = \sum_{j=1}^L |\langle \varphi_j, e_i \rangle|^2 = \frac{L}{M}.
\]

That is, the columns of \( A = \left\{ \varphi_j \right\}_{j=1}^L \) all have the same square sums.

Moreover, the angle between \( (I - P)e_i \) and \( (I - P)e_j \) is given by the inner product of the \( i \)th and \( j \)th columns of \( \left\{ \varphi_j \right\}_{j=1}^L \).

**Proof.** (1) \( \iff \) (2): We know that \( \{(I - P)e_i\}_{i=1}^M \) is equal-norm if and only if \( \{Pe_i\}_{i=1}^M \) which, in turn, is equal-norm if and only if the diagonal elements of the matrix for \( P \) relative to \( \{e_i\}_{i=1}^M \) have constant modulus. We have,

\[
P e_i = \sum_{n=1}^L \langle e_i, \varphi_n \rangle \varphi_n = \sum_{n=1}^M \left( \sum_{m=1}^L \langle e_i, \varphi_n \rangle \langle \varphi_n, e_m \rangle \right) e_m.
\]
The diagonal element of $Pe_i$ is:
\[
\sum_{n=1}^{L} \langle e_i, \varphi_n \rangle \langle \varphi_n, e_i \rangle = \sum_{n=1}^{L} |\langle \varphi_n, e_i \rangle|^2.
\]
So $\{Pe_i\}_{i=1}^{M}$ is an equal-norm tight frame if and only if for all $1 \leq i, j \leq M$ we have
\[
\sum_{n=1}^{L} |\langle \varphi_n, e_i \rangle|^2 = \sum_{n=1}^{L} |\langle \varphi_n, e_j \rangle|^2.
\]
For the moreover part, we compute for $1 \leq i \neq j \leq M$:
\[
\langle (I - P)e_i, (I - P)e_j \rangle = \langle e_i, e_j \rangle - \langle Pe_i, e_j \rangle - \langle e_i, Pe_j \rangle + \langle Pe_i, Pe_j \rangle
\]
\[
= \langle Pe_i, Pe_j \rangle = \langle e_i, Pe_j \rangle
\]
\[
\langle e_i, \sum_{n=1}^{L} \langle e_j, \varphi_n \rangle \varphi_n \rangle = \langle e_i, \sum_{m=1}^{M} \left( \sum_{n=1}^{L} \langle e_j, \varphi_n \rangle \langle \varphi_n, e_m \rangle \right) e_m \rangle = \sum_{n=1}^{L} \langle e_j, \varphi_n \rangle \langle \varphi_n, e_i \rangle.
\]
The right-hand side of the above equality is precisely the inner product of the $i$th and $j$th columns of $\{\varphi_j\}_{j=1}^{L}$. \qed

The following consequence of the above is surprising at first. It says that we can almost never get (in the real case) frames robust to $k$ erasures by stepping down from frames robust to one erasure, then to frames robust to two erasures etc.

**Corollary 5.4.** In the real case, if $M \geq 3$, there do not exist rank-1 orthogonal projections $P_1, P_2$ with $P_1 P_2 = 0$ so that $\{(I - P_1)e_i\}_{i=1}^{M}$ is equal-norm and $\{(I - P_2)(I - P_1)e_i\}_{i=1}^{M}$ is equal-norm and robust to two erasures.

**Proof.** Assume such $P_1, P_2$ exist. Since $\{(I - P_1)e_i\}_{i=1}^{M}$ is equal-norm, by Theorem 5.2, there is a vector $\varphi_1 = \sum_{i=1}^{M} a_i e_i \in \mathbb{H}_M$ with $P_1 f = \langle f, \varphi_1 \rangle \varphi_1$, for all $f \in \mathbb{H}_M$ and $|a_i| = |a_j|$, for all $1 \leq i, j \leq M$. Now choose $\varphi_2 = \sum_{i=1}^{M} b_i e_i \in \mathbb{H}_M$ so the $P_2 f = \langle f, \varphi_2 \rangle \varphi_2$, for all $f \in \mathbb{H}_M$. Since $P_1, P_2$ are rank-1, $P_1 P_2 = 0$ implies $P_2 P_1 = 0$. That is, $\langle \varphi_1, \varphi_2 \rangle = 0$. Let $P = P_1 + P_2$. Then $(I - P_2)(I - P_1) = I - P$. Since $\{(I - P)e_i\}_{i=1}^{M}$ is equal-norm, by Theorem 5.2 we have
\[
a_i^2 + b_i^2 = a_j^2 + b_j^2, \quad \text{for all} \quad a \leq i, j \leq M.
\]
Hence, $b_i^2 = b_j^2$, for all $1 \leq i, j \leq M$. Since $||\varphi_1|| = ||\varphi_2|| = 1$, it follows that
\[
a_i^2 = b_i^2 = \frac{1}{M}, \quad \text{for all} \quad 1 \leq i, j \leq M.
\]
Since $\{(I - P)e_i\}_{i=1}^{M}$ is robust to two erasures, by Theorem 5.2
\[
a_i b_j - a_j b_i \neq 0, \quad \text{for all} \quad 1 \leq i, j \leq M.
\]
However, for all $i, j$ we have $a_i = \pm a_j = \pm b_i$. Hence, there is some $i, j$ with either $a_i = a_j$ and $b_i = b_j$ or $a_i = -a_j$ and $b_i = -b_j$. In either case (29) fails. □

Corollary 5.4 is heavily dependent on having a real Hilbert space. In the complex case, we will show in Corollary 5.6 that the GHFs have the property that we can step down to the frame by successively applying rank-1 projections to the orthonormal basis. Corollary 5.4 shows that in general we cannot step down one dimension at a time to construct frames robust to $k$ erasures. It would be interesting to extend this to a classification of when we can step down from $k_1$ erasures to $k_2$ erasures and so on. One reason is that this has implications for entangled states in quantum detection theory [12, 22].

This raises the question of whether we can step down one dimension at a time as in Corollary 5.4 if we only ask for each level to be equal-norm. The answer is no as the next example shows.

**Example 5.1.** Let $\{e_i\}_{i=1}^4$ be an orthonormal basis for $\mathbb{H}_4$ and let

$$\varphi_1 = \frac{1}{\sqrt{2}} e_1 + \frac{1}{2} e_3 + \frac{1}{2} e_4,$$

and

$$\varphi_2 = \frac{1}{\sqrt{2}} e_2 + \frac{1}{2} e_3 - \frac{1}{2} e_4.$$

Then $\langle \varphi_1, \varphi_2 \rangle = 0$, and if $P$ is the orthogonal projection of $\mathbb{H}_4$ onto the span of $\{\varphi_1, \varphi_2\}$, then by Theorem 5.2, $\{(I-P)e_i\}_{i=1}^4$ is a equal-norm Parseval tight frame. However, there does not exist a rank-1 orthogonal projection $P_1$ of $\mathbb{H}_4$ into range of $P$ so that $\{(I-P_1)e_i\}_{i=1}^4$ is a equal-norm frame.

**Proof.** By Theorem 5.2, in order for such a $P_1$ to exist, there must exist a vector in $P\mathbb{H}_4$ of the form $\sum_{i=1}^4 b_i e_i$ with $|b_i| = |b_j|$, for all $1 \leq i, j \leq 4$. For any $a_1, a_2$,

$$a_1 \varphi_1 + a_2 \varphi_2 = \frac{a_1}{\sqrt{2}} e_1 + \frac{a_2}{\sqrt{2}} e_2 + \frac{a_1 + a_2}{2} e_3 + \frac{a_1 - a_2}{2} e_4.$$

If $(|a_1 + a_2|)/2 = (|a_1 - a_2|)/2$, then one of $|a_1|, |a_2|$ equals 0 so $|a_1| \neq |a_2|$. □

The next question is whether we can step down one dimension at a time as in Corollary 5.4 if all we want is for our frame to be robust to $j$ erasures at the $j$th level but are willing to give up the requirement of equal-norm at each level. Surprisingly, the answer here is yes.

**Proposition 5.5.** Let $P$ be an orthogonal projection of $\mathbb{H}_M$ onto an $L$-dimensional subspace $\mathbb{H}_L$. Let $\{e_i\}_{i=1}^M$ be an orthonormal basis for $\mathbb{H}_M$. If $\{(I-P)e_i\}_{i=1}^M$ is robust to $k$ erasures ($k \leq L$), then there are mutually orthogonal rank-1 projections $\{P_j\}_{j=1}^L$ taking $\mathbb{H}_M$ into $\mathbb{H}_L$ so that $\{(I-P_j)(I-P_{j-1}) \cdots (I-P_1)e_i\}_{i=1}^M$ is robust to $j$ erasures, for all $1 \leq j \leq k$, and robust to $k$ erasures for all $k \leq j \leq L$.

**Proof.** See Appendix A.3. □
5.3. ENTFs Robust to More than One Erasure: An Alternative Approach

In the previous sections we used the orthogonal projection $P$ on $H_M$ to classify when $\{(I - P)e_i\}^{M}_{i=1}$ is robust to $k$ erasures and when it is equal-norm. However, if the dimension of $P H_M$ is large (that is, close to the dimension of $H_M$) these results become difficult to implement since they require knowledge about the orthonormal bases for the large-dimensional space $P H_M$. In this case, $\{(I - P)e_i\}^{M}_{i=1}$ is a large number of vectors in a small-dimensional space $(I - P)H_M$. So it is easier in this case to work directly with $(I - P)H$ and $\{(I - P)e_i\}$. Or, equivalently, with $PH$ and $\{Pe_i\}$, where $\dim PH$ is small.

**Proposition 5.6.** Let $\{\varphi_i\}^N_{i=1}$ be an orthonormal sequence in $H_M$, let $\{e_i\}^M_{i=1}$ be an orthonormal basis for $H_M$ and let $P$ be the orthogonal projection of $H_M$ onto the span of $\{\varphi_i\}^N_{i=1}$. Then the Parseval tight frame $\{Pe_i\}^M_{i=1}$ is unitarily equivalent to $\{g_i\}^M_{i=1}$ where for $1 \leq j \leq M$ we have

$$g_j = \sum_{i=1}^{N} \langle \varphi_i, e_j \rangle e_i.$$

That is, $\{Pe_i\}^M_{i=1}$ is the frame obtained by turning the columns of $\{\varphi_i\}^N_{i=1}$ into row vectors in $H_N$.

**Proof.** For any $1 \leq i \leq M$ we have:

$$Pe_i = \sum_{n=1}^{L} \langle e_i, \varphi_n \rangle \varphi_n.$$

Since $\{\varphi_n\}^L_{n=1}$ is an orthonormal sequence, the operator $T \varphi_n = e_n$, for $1 \leq n \leq L$ is a unitary operator which takes $Pe_i$ to $\{g_j\}^M_{j=1}$ where for $1 \leq j \leq M$ and we have

$$g_j = \sum_{i=1}^{N} \langle \varphi_i, e_j \rangle e_i.$$

\]

**Corollary 5.5.** Given the conditions in Proposition 5.6 we have:

1. $\{g_j\}^M_{j=1}$ is an equal-norm frame for $H_N$ if and only if

$$\sum_{i=1}^{N} |\langle \varphi_i, e_j \rangle|^2 = \frac{N}{M}, \quad \text{for all} \quad 1 \leq j \leq M.$$

2. The following are equivalent:

(a) $\{g_j\}^M_{j=1}$ is robust to the erasure of $\{g_j\}_{j \in I}$ for some $I \subset \{1, 2, \cdots M\}$.

(b) We have that

$$\langle \varphi_i, e_j \rangle^{N}_{i=1, j \in I}$$

has row rank $N$. 

Hence, \( \{ g_j \}_{j=1}^M \) is robust to any choice of \( k \) erasures, \( k \leq M - N \), if and only if every set of \( M - k \) columns of the matrix

\[
A = (\langle \varphi_i, e_j \rangle)_{i=1, j=1}^{N, M}
\]

has row rank \( N \).

Finally, the angle between \( g_i \) and \( g_j \) is given by the inner product of the \( i \)th and \( j \)th columns of \( A \).

It would be interesting and useful to classify the GHFs in the format of this section. That is, precisely when is \( \{(I - P)e_i\}_{i=0}^{M-1} \) a GHF? One important property of GHFs is contained in the following result which says they have the step-down property of Section 5.1.

**Corollary 5.6.** Let \( P \) be an orthogonal projection of \( \mathbb{H}_M \) onto an \( L \)-dimensional subspace \( \mathbb{H}_L \) and let \( \{e_i\}_{i=0}^{M-1} \) be an orthonormal basis for \( \mathbb{H}_M \). If \( \{(I - P)e_i\}_{i=0}^{M-1} \) is a GHF then there is an orthogonal sequence of rank-1 projections \( \{P_i\}_{i=0}^{L-1} \) of \( \mathbb{H}_M \) into \( \mathbb{H}_L \) so that for all \( 1 \leq j \leq L \) and for all permutations \( \sigma \) of \( \{1, 2, \cdots, L\} \) we have that

\[
\prod_{m=0}^{j-1} (I - P_{\sigma(m)})e_i \right\}_{i=0}^{M-1}
\]

is a GHF and hence is an ENPTF which is robust to \( j \) erasures. Here, \( P_{\sigma(m)} = P_i \) for \( i = \sigma(m) \).

**Proof.** We will do the proof for HTFs since the GHF case requires only notational changes but obscures the basic ideas of the proof. By Proposition 5.6, there is a unique way to get HTFs. Namely, let \( \{e_i\}_{i=0}^{M-1} \) be the natural orthonormal basis for \( \mathbb{H}_M \). Let \( \{w_i\}_{i=0}^{M-1} \) be distinct \( M \)th roots of unity and consider the orthonormal basis \( \{\varphi_i\}_{i=0}^{M-1} \) for \( \mathbb{H}_M \) given by:

\[
\varphi_i = \sum_{j=0}^{M-1} w_i^j e_j.
\]

Without loss of generality, we may as well assume that \( \mathbb{H}_L = \text{span} \{\varphi_i\}_{i=0}^{L} \). Now, turning the row vectors of \( \{\varphi_i\}_{i=0}^{M-1} \) into column vectors gives an HTF for \( \mathbb{H}^{M-L} \). Moreover, again by Proposition 5.6, this HTF is unitarily equivalent to \( \{(I - P)e_i\}_{i=0}^{M-1} \) where \( I - P \) is the orthogonal projection onto \( (\mathbb{H}_L)^\perp \). Now, let \( P_i \) be the orthogonal rank-1 projection of \( \mathbb{H}_M \) onto \( \text{span} \varphi_i \) for \( 0 \leq i \leq L - 1 \). Fix a permutation \( \sigma \) of \( \{1, 2, \cdots, L\} \) and let \( I_j = \{\sigma(0), \sigma(1), \cdots, \sigma(j - 1)\} \). Then, again by Proposition 5.6,

\[
\prod_{m=0}^{j-1} (I - P_{\sigma(m)})e_i \right\}_{i=0}^{M-1},
\]

is unitarily equivalent to the HTF obtained by turning the row vectors of \( \{\varphi_i\}_{i\in I_j} \) into column vectors. ■
It is possible that the property in Corollary 5.6 characterizes GHFs, but we do not have a proof for this. We can show that the use of permutations is necessary in Proposition 5.6. That is, there are ENPTFs which have the step-down property for erasures and for being equal-norm for one fixed ordering of the rank-1 projections $P_i$ while failing to be equivalent to a GHF. This is the point of the next example.

**Example 5.2.** In $\mathbb{C}^4$, let

$$
\varphi_1 = \sum_{i=1}^{4} e_i, \quad \varphi_2 = \sum_{i=1}^{4} w_i e_i, \quad \varphi_3 = e_1 + e_2 - e_3 - e_4,
$$

where $w_1 = 1, w_2 = -1, w_3 = i$ and $w_4 = -i$. Let $\{P_i\}_{i=1}^{3}$ be the rank-1 orthogonal projections of $\mathbb{C}^4$ onto the span of $\varphi_i$. Then it follows easily from our results that:

1. $\{(I - P_1)e_i\}_{i=1}^{4}$ is an ENPTF which is robust to one erasure.
2. $\{(I - P_2)(I - P_1)e_i\}_{i=1}^{4}$ is a ENPTF which is robust to 2 erasures.
3. $\{(I - P_3)(I - P_2)(I - P_1)e_i\}_{i=1}^{4}$ is an ENPTF which is robust to 3 erasures, but is not a harmonic frame since $\{(I - P_3)(I - P_1)e_i\}_{i=1}^{4}$ is an ENPTF which is not robust to 2 erasures.

**Example 5.3.** If $\varphi_i = (1, w_i)$ in $\mathbb{C}^2$ for $1 \leq i \leq M$, where $|w_i| = 1$ and the $\{w_i\}_{i=1}^{M}$ are distinct, then $\{\varphi_i\}_{i=1}^{M}$ is an ENPTF for $\mathbb{C}^2$ if and only if $\sum_{i=1}^{M} w_i = 0$. If $M = 3$, $\varphi_i = (1, 2i, -i)$ is an ENPTF for $\mathbb{C}^2$ by Proposition 5.6. In this case, $P_2$ is an orthogonal rank-1 projection onto the span $\varphi_i$, then $\{(I - P_2)e_i\}_{i=1}^{M}$ is an ENPTF which is robust to one erasure while $\{(I - P_j)(I - P_i)e_i\}_{i=1}^{M}$ is an ENPTF which is robust to 2 erasures for all $1 \leq j \neq k \leq M$.

**Proof.** This set is certainly equal-norm. The assumption $\sum_{i=1}^{M} w_i = 0$ guarantees that the vectors

$$(1, 1, 1, \cdots, 1) \text{ and } (w_1, w_2, \cdots, w_M)$$

are orthogonal in $\mathbb{H}_M$ (and conversely). Hence, $\{\varphi_i\}_{i=1}^{M}$ is an ENPTF for $\mathbb{C}^2$ by Proposition 5.6. □

**Example 5.4.** In general, the frames constructed in Example 5.3 are not equivalent to harmonic frames even after a permutation.

**Proof.** The reason is that $\{\varphi_j\}_{j=0}^{M-1}$ is a GHF implies that

$$\langle \varphi_j, \varphi_{j+1} \rangle = \langle \varphi_{j+1}, \varphi_{j+2} \rangle \text{ for all } 0 \leq j \leq M - 2,$$

(see Proposition 2.5). This would imply in Example 5.3 that

$$\langle \varphi_j, \varphi_{j+1} \rangle = 1 + w_j w_{j+1} = 1 + w_{j+1} w_{j+2} = \langle \varphi_{j+1}, \varphi_{j+2} \rangle.$$ 

Hence, $w_j w_{j+1} = w_{j+1} w_{j+2}$. Now, let $w_1 = 1$, $w_2 = -1/2 + \sqrt{3}/4i$ and $w_2 = -1/2 - \sqrt{3}/4i$. Then $|w_j| = 1$ and $\sum_{j=1}^{3} w_j = 0$. Hence, by Example 5.3,
{(1, w_j)}_{j=1}^3 \text{ is an ENPTF for } \mathbb{C}^2. \text{ However, for any permutation } \sigma \text{ of } \{1, 2, 3\},
we do not have } w_{\sigma(j)} \overline{w_{\sigma(j+1)}} = w_{\sigma(j+1)} \overline{w_{\sigma(j+2)}}, \text{ for all } 0 \leq j \leq 2 (\text{with } w_4 = w_1). \quad \blacksquare
It is not hard to see that in the case of } \mathbb{R}^2, \text{ the condition in Corollary 5.6 is sufficient.}

6. CONCLUDING REMARKS
The results in this paper were motivated by our wish to find the “perfect frames”,
at least for the applications of transmission with losses. Prior to embarking on this
work, the best frames we knew of were the HTFs; that is the case still. The
HTFs remain the most computationally efficient, the ones with most structure
(group structure) as well as the only good example we know of which remain frames
with any number of up to } M - N \text{ erasures. Thus our search for “perfect frames”
continues...}

APPENDIX: PROOFS

A.1. PROOF OF PROPOSITION 4.1
First note that if } \{c_k\}_{k=1}^N \text{ are distinct } M\text{th roots of } c \text{ with } |c| = 1, \text{ then}
\[ \sum_{i=0}^{M-1} c_k^i = 0, \quad \sum_{i=0}^{M-1} |c_k|^2 = M, \quad \sum_{i=0}^{M-1} (c_k c_l)^i = 0, \] \quad (A.1)
and thus
\[ \sum_{i=0}^{M-1} (c_k c_l)^i = M \delta_{kl}. \] \quad (A.2)
We now check the necessity of our condition for a frame to be a general harmonic
frame. If } \{\psi_i\}_{i=1}^M \text{ is a general harmonic frame for } \mathbb{H}_N \text{ then there exists a unitary
operator } V \text{ on } \mathbb{H}_N \text{ with } V \psi_k = \varphi_k \text{ and by the definition:}
\[ \varphi_i = (c_1^i b_1, c_2^i b_2, \cdots, c_N^i b_N) = \sum_{k=1}^N c_k^i b_k e_k, \]
where } \{e_k\}_{k=1}^N \text{ is the natural unit vector orthonormal basis of } \mathbb{H}_N, \text{ } |b_k| = 1/\sqrt{M},
and } \{c_k\}_{k=1}^N \text{ are distinct } M\text{th roots of } c \text{ with } |c| = 1. \text{ Now let}
\[ \varphi_0 = \sum_{k=1}^N b_k e_k. \]
Define a unitary operator } U \text{ on } \mathbb{H}_N \text{ by } U e_k = c_k e_k. \text{ Then, for all } 0 \leq i \leq M - 1
we have } U^i e_k = c_k^i e_k, \text{ and thus, } U^i \varphi_0 = \varphi_i \text{ for all } 0 \leq i \leq M - 1. \text{ So our frame has
the form given in the proposition.}
The sufficiency of the condition is checked similarly. If we assume that } \{\varphi_i\} \text{ is of
the form described in the proposition, then:}
\[ ||\varphi_i|| = ||U^i \varphi_0|| = ||\varphi_0|| = \sqrt{\frac{N}{M}}, \]
since $U$ is a unitary operator. So $\{\varphi_i\}$ is an equal-norm frame. To see that $\{\varphi_i\}$ is a Parseval tight frame, we let $f = \sum_{k=1}^{N} a_k e_k \in \mathbb{H}_N$ and compute:

$$
\sum_{i=0}^{M-1} |\langle f, U^i \varphi_0 \rangle|^2 = \sum_{i=0}^{M-1} \left| \sum_{k=1}^{N} a_k c_k^i b_k \right|^2 = \sum_{i=0}^{M-1} \sum_{k=1}^{N} |a_k c_k^i b_k|^2 + \sum_{m \neq \ell} a_m \overline{b_\ell} \sum_{i=0}^{M-1} (c_m c_\ell)^i = M \sum_{k=1}^{N} |a_k|^2 |b_k|^2 + 0 = M \sum_{k=1}^{N} |a_k|^2 \frac{1}{\sqrt{M}} = ||f||^2,
$$

where in the next to last equality we used the fact that the $\{c_k\}$ is a set of distinct $M$th roots of $c$ (see (A.2)). Hence, $\{\varphi_i\}$ is an ENPTF. Thus, using (15) and writing $f = e_j$, we see that

$$
||e_j||^2 = 1 = \sum_{i=1}^{M} |\langle e_j, U^i \varphi_0 \rangle|^2 = \sum_{i=1}^{M} |\langle e_j, \sum_{k=1}^{N} c_k^i b_k e_k \rangle|^2 = \sum_{i=1}^{M} |c_j^i b_j|^2 = M |b_j|^2.
$$

So $|b_j| = 1/\sqrt{M}$, for all $j, 0 \leq j \leq N - 1$. This further means that

$$
\varphi_0 = (b_1, b_2, \ldots, b_N)
$$

with $|b_j| = 1/\sqrt{M}$ and since $\varphi_i = U^i \varphi_0$,

$$
\varphi_i = (c_1^i b_1, c_2^i b_2, \ldots, c_N^i b_N).
$$

**A.2. PROOF OF THEOREM 4.1**

We prove the theorem in steps.

**Step 1:** We first prove that there is a constant $|c| = 1$ so that $U^M = cI$. This will show that the operators $\{U^i\}_{i=0}^{M-1}$, in fact, form a group with a single generator. Since the frame is a PTF, for every $f \in \mathbb{H}_N$ we have,

$$
f = \sum_{i=0}^{M-1} \langle f, U^i \varphi_0 \rangle U^i \varphi_0.
$$

Hence,

$$
U f = \sum_{i=0}^{M-1} \langle U f, U^i \varphi_0 \rangle U^i \varphi_0 = \sum_{i=0}^{M-1} \langle f, U^{i-1} \varphi_0 \rangle U^i \varphi_0, \quad \text{since } U^* = U^{-1},
$$

$$
= U \left( \sum_{i=0}^{M-1} \langle f, U^{i-1} \varphi_0 \rangle U^{i-1} \varphi_0 \right) = U \left( \sum_{i=-1}^{M-2} \langle f, U^i \varphi_0 \rangle U^i \varphi_0 \right). \quad (A.3)
$$
Since $U$ is one-to-one,

$$f = \sum_{i=-1}^{M-2} \langle f, U^i \varphi_0 \rangle U^i \varphi_0 = \sum_{i=0}^{M-1} \langle f, U^i \varphi_0 \rangle U^i \varphi_0. \quad (A.4)$$

From (A.3) and (A.4), it follows that,

$$\langle f, U^{M-1} \varphi_0 \rangle U^{M-1} \varphi_0 = \langle f, U^{-1} \varphi_0 \rangle U^{-1} \varphi_0.$$ 

Applying $U$ we have

$$\langle f, U^{M-1} \varphi_0 \rangle U^M \varphi_0 = \langle f, U^{-1} \varphi_0 \rangle U^0 \varphi_0 = \langle f, U^{-1} \varphi_0 \rangle \varphi_0. \quad (A.5)$$

Hence, there is a $c \in \mathbb{C}$ so that $U^M \varphi_0 = c \varphi_0$. Replacing $f$ by $U^{-1} f$ in (A.5) gives:

$$\langle U^{-1} f, U^{M-1} \varphi_0 \rangle U^M \varphi_0 = \langle f, U^M \varphi_0 \rangle U^M \varphi_0 = \langle f, U^M \varphi_0 \rangle \varphi_0 = c^2 \langle f, \varphi_0 \rangle \varphi_0 = (U^{-1} f, U^{-1} \varphi_0) \varphi_0 = \langle f, \varphi_0 \rangle \varphi_0.$$

So $|c|^2 = 1$. Also, for all $0 \leq i \leq M-1$,

$$U^M U^i \varphi_0 = U^i U^M \varphi_0 = U^i c \varphi_0 = c U^i \varphi_0.$$ 

Since \{\text{\textit{U}}^i \varphi_0\} spans \text{\textsc{h}}_{\mathbb{N}}$, that is, for any $f \in \text{\textsc{h}}_{\mathbb{N}}$ $f = \sum_i \langle f, U^i \varphi_0 \rangle U^i \varphi_0$, it follows that $U^M = c \text{\textit{I}}$. This completes Step I.

\textit{Step II}: We want to prove:

1. $U$ is diagonalizable with respect to an orthonormal basis \{\textit{e}$_k$\}$^N_{k=1}$ with diagonal elements \{\textit{c}$_k$\}$^N_{k=1}$ with $\textit{c}$_k$ an $M$th root of $c$.

2. $\varphi_0 = \sum_{k=1}^{N} b_k \textit{e}_k$ and $|b_k| = \sqrt{1/M}$, for all $1 \leq k \leq N$.

These two steps give us frame elements as in Definition 2.1.

Since $U$ is unitary (and hence normal), and our space is finite dimensional, it follows that $U$ is diagonalizable with respect to an orthonormal basis \{\textit{e}$_k$\}$^N_{k=1}$ with diagonal elements \{\textit{c}$_k$\}$^N_{k=1}$. Writing $\varphi_0$ as in 2., we have that

$$U^i \varphi_0 = \sum_{k=1}^{N} c^i_k b_k \textit{e}_k.$$ 

Since $U^M = c \text{\textit{I}}$, it follows that each $c_k$ is an $M$th root of $c$. Also, since the frame is a PTF, for all $1 \leq j \leq N$ we have

$$1 = \sum_{i=1}^{M} |\langle e_j, U^i \varphi_0 \rangle|^2 = \sum_{i=1}^{M} |\langle e_j, \sum_{k=1}^{N} c^i_k b_k \textit{e}_k \rangle|^2 = \sum_{k=1}^{N} |c^j_k b_k|^2 = M |b_j|^2.$$ 

So $|b_j| = 1/\sqrt{M}$. This completes Step II.
**Step III:** We finally prove that the $c_k$ are distinct $M$th roots of $c$. This will complete the proof.

Fix $1 \leq m \neq \ell \leq M$. Since the columns of a Parseval tight frame are orthogonal vectors, that is, $F^* F = I$, we have for columns $m, \ell$,

$$0 = \sum_{i=0}^{M-1} b_m c_m^i \overline{b_\ell c_\ell^i} = b_m \overline{b_\ell} \sum_{i=0}^{M-1} (c_m c_\ell^i)^i.$$

Hence,

$$\sum_{i=0}^{M-1} (c_m c_\ell^i)^i = 0.$$

Thus, $c_m$ and $c_\ell$ are distinct $M$th roots of $c$. This completes the proof of Step III and the theorem.

**A.3. PROOF OF PROPOSITION 5.5**

For all $1 \leq j \leq L$, let

$$g_j = \sum_{i=1}^M \langle g_j, e_i \rangle e_i,$$

be an orthonormal basis for $\mathbb{H}_L$. We will construct the projections $\{P_j\}_{j=1}^L$ by finite induction. We start with $P_1$. Since $\{(I-P)e_i\}_{i=1}^M$ is robust to 1 erasure, by Theorem 5.1, for every $1 \leq i \leq M$ there exists a $1 \leq j \leq L$ so that $\langle g_j, e_i \rangle \neq 0$. Choose scalars $a_1, a_2, \ldots, a_L$ so that for any $1 \leq j \leq L$, if $\langle g_j, e_i \rangle \neq 0$ for some $1 \leq i \leq M$, then

$$|a_j \langle g_j, e_i \rangle| \geq 2 \sum_{k=1}^{j-1} |a_k \langle g_k, e_i \rangle|.$$

It follows easily that

$$\varphi_1 = \frac{\sum_{j=1}^j a_j g_j}{\| \sum_{j=1}^j a_j g_j \|},$$

then $\langle \varphi_1, e_i \rangle \neq 0$, for all $1 \leq i \leq M$. Now, let $P_1$ be the orthogonal projection onto the span $\{\varphi_1\}$, then $\{(I-P_1)e_i\}_{i=1}^M$ is robust to 1 erasure by Corollary 5.1.

Now assume we have found orthonormal vectors $\{\varphi_j\}_{j=1}^n$, $n < k - 1$ so that the rank-1 projections $P_j$ onto span $\{\varphi_j\}$ satisfy the proposition and span $\{\varphi_j\}_{j=1}^n = \text{span} \{g_j\}_{j=1}^n$. We will construct $\varphi_{n+1}$ and $P_{n+1}$. Let $\{g_j\}_{j=1}^L$ be an orthonormal basis for the orthogonal complement of span $\{\varphi_j\}_{j=1}^n$ in $\mathbb{H}_L$. Fix $1 \leq i_1 < i_2 < \cdots < i_{n+1} \leq M$. Since

$$\{(I-P_{i_1})(I-P_{i_2}) \cdots (I-P_L)e_i\}_{i=1}^M$$

is robust to $n$ erasures, if we row reduce $\{\varphi_j\}_{j=1}^n$ using the columns $\{i_1, i_2, \ldots, i_n\}$ (and switching rows if necessary) we obtain vectors $\{h_j\}_{j=1}^n$ with span $\{h_j\}_{j=1}^n = \text{span} \{\varphi_j\}_{j=1}^n$ and for every $1 \leq j \leq n$ we have,

$$\langle h_j, e_{i_j} \rangle = \delta_{j, i_j}.$$
Now we verify the following claim:

**Claim:** For all but finitely many \(0 < x < 1\), if

\[
h_{n+1} = \sum_{j=n+1}^{L} x^j g_j,
\]

then the row rank of

\[
(\langle h_j, e_{i_\ell} \rangle)_{j=1}^{n+1},
\]

is \(n + 1\).

**Proof of Claim** Fix \(0 < x < 1\). We row reduce this matrix by taking, for all \(1 \leq \ell \leq M\),

\[
-\left( \sum_{j=n+1}^{L} x^j g_j, e_{i_\ell} \right) h_{\ell} + h_{n+1}.
\]

We then arrive at a matrix with 1s in the \(j\)th row and the \(i_\ell\)th column for \(1 \leq j \leq n\), zeroes otherwise, zeroes in the \((n + 1)\)st row for columns \(i_j\) for all \(1 \leq j \leq n\), and in the \((n + 1, n + 1)\)st position we have:

\[
\langle h_{n+1}, e_{i_{n+1}} \rangle - \sum_{\ell=1}^{n} \left( \sum_{j=n+1}^{L} x^j g_j, e_{i_\ell} \right) \langle h_{\ell}, e_{i_\ell} \rangle.
\]

If this number is nonzero, then our matrix is of rank \(n + 1\). Now we check what it takes for this to be nonzero.

\[
\langle h_{n+1}, e_{i_{n+1}} \rangle - \sum_{\ell=1}^{n} \left( \sum_{j=n+1}^{L} x^j g_j, e_{i_\ell} \right) \langle h_{\ell}, e_{i_\ell} \rangle
\]

\[
= \sum_{j=n+1}^{L} x^j \langle g_j, e_{i_{n+1}} \rangle - \sum_{j=n+1}^{L} x^j \sum_{j=1}^{n} \langle g_j, e_{i_\ell} \rangle \langle h_{\ell}, e_{i_\ell} \rangle
\]

\[
= \sum_{j=n+1}^{L} x^j \left[ \langle g_j, e_{i_{n+1}} \rangle - \sum_{\ell=1}^{n} \langle g_j, e_{i_\ell} \rangle \langle h_{\ell}, e_{i_\ell} \rangle \right].
\]

By the hypotheses on the proposition,

\[
(\langle g_j, e_{i_\ell} \rangle)_{j=1}^{n+1},
\]

has rank \(n + 1\). It follows that there is a \(n + 1 \leq j \leq L\) so that

\[
\langle g_j, e_{i_{n+1}} \rangle - \sum_{\ell=1}^{n} \langle g_j, e_{i_\ell} \rangle \langle h_{\ell}, e_{i_\ell} \rangle \neq 0.
\]

Hence, the number of \(x\)’s with

\[
\langle h_{n+1}, e_{i_{n+1}} \rangle - \sum_{\ell=1}^{n} \left( \sum_{j=n+1}^{L} x^j g_j, e_{i_\ell} \right) \langle h_{\ell}, e_{i_\ell} \rangle = 0,
\]
is finite. This establishes the claim.
Applying the claim to all choices of \(1 \leq i_1 < i_2 < \cdots < i_{n+1} \leq M\), we see that for all but finitely many \(0 < x < 1\), for all \(1 \leq i_1 < i_2 < \cdots < i_{n+1} \leq L\), the rank of \(\left(\langle h_j, e_{i_j} \rangle \right)_{j=1, \ell=1}^{M, n+1}\) is \(n + 1\). Let
\[
\varphi_{n+1} = \frac{h_{n+1}}{\|h_{n+1}\|},
\]
and let \(P_{n+1}\) be the orthogonal projection of \(\mathbb{H}_M\) onto \(\text{span} \{\varphi_{n+1}\}\). Now,
\[
\left\{(I - P_{n+1})(I - P_n) \cdots (I - P_1)e_i\right\}_{i=1}^M
\]
is robust to \((n + 1)\) erasures by Theorem 5.1. This completes the proof of the proposition.

ACKNOWLEDGMENT
The first author would like to thank V. Paulsen for fruitful discussions.
